Pinching Implies Strong Pinching

by HERMANN KARCHER¹⁾

The author was led to look for bounds as in (2) by a preprint manuscript of the article by E. Ruh which precedes this paper. Denote by δ the minimum, by Δ the maximum of the sectional curvatures at $p \in M$ ($\dim M = n$) and by λ the smallest, by Λ the largest eigenvalue of the curvature operator $\varrho: M_p \wedge M_p \rightarrow M_p \wedge M_p$ (defined by $\varrho\omega(X, Y) := \text{trace}_Z \omega(R(X, Y)Z, Z)$ in terms of the curvature tensor R of the Riemannian metric on M).

It is well known that $\lambda \leq 2\delta$ and $2\Delta \leq \Lambda$. We prove:

$$\text{trace } \varrho = \sum_{i \neq k} \langle R(X_i, X_k) X_k, X_i \rangle = \text{scalar curvature.} \quad (1)$$

$$\left. \begin{aligned} \Delta + \delta - \frac{2}{3}(\Delta - \delta)[n(n-1)(n+\frac{1}{4})]^{1/2} &\leq \lambda \leq \Lambda \leq \\ \Delta + \delta + \frac{2}{3}(\Delta - \delta)[n(n-1)(n+\frac{1}{4})]^{1/2}. \end{aligned} \right\} \quad (2)$$

From (2) and Ruh's theorem [3] we have the

COROLLARY. *A complete simply connected Riemannian manifold with $\delta/\Delta \geq 1 - [\frac{1}{2} + \frac{5}{3}(n(n-1)(n+\frac{1}{4}))^{1/2}]^{-1}$ has $\lambda/\Lambda \geq \frac{2}{3}$, hence is diffeomorphic to the standard sphere*

Remark. The numerical values are worse than the ones obtained by Gromoll (explicitly computed up to $n=12$); for example for $n=7$ resp. $n=12$ we need $\delta/\Delta \geq 0.966$ resp. 0.985, Gromoll's figures are 0.819 resp. 0.931.

Proof. Use a normal coordinate system at $p \in M$ with associated basis X_i ($i=1, \dots, n$) of M_p . For $\omega \in M_p \wedge M_p$, put $\omega_{ik} = \omega(X_i, X_k)$, hence $\omega = \frac{1}{2} \sum_{i \neq k} \omega_{ik} X_i \wedge X_k$. The scalar product in $M_p \wedge M_p$ is given by $\langle \omega, \bar{\omega} \rangle = \frac{1}{2} \sum_{i \neq k} \omega_{ik} \bar{\omega}_{ik}$.

We have

$$\varrho(X_i \wedge X_j)(X_k, X_l) = 2R_{klji} = \langle \varrho(X_i \wedge X_j), X_k \wedge X_l \rangle, \quad (3)$$

hence

$$\begin{aligned} \langle \varrho\omega, \omega \rangle &= \frac{1}{2} \sum' R_{klji} \omega_{ij} \omega_{kl} \\ &\left(\sum' = \sum_{k \neq l, i \neq j} \text{ here and below} \right) \end{aligned} \quad (4)$$

(3) and (4) imply $\lambda \leq 2\delta$ and $2\Delta \leq \Lambda$, but (3) shows also that the eigenvectors ω^v ($v=1, \dots, \frac{1}{2}n(n-1)$) of ϱ are in general not forms of rank 2 so that the reversed inequalities

¹⁾ This paper was prepared under the program "Sonderforschungsbereich Theoretische Mathematik" at Bonn University.

cannot be expected. (4) implies (1) immediately:

$$\begin{aligned}\text{trace } \varrho &= \sum_v \langle \varrho \omega^v, \omega^v \rangle = \frac{1}{2} \sum' R_{klji} \sum_v \omega_{ij}^v \omega_{kl}^v \\ &= \frac{1}{2} \sum' R_{klji} (\delta_{ik} \delta_{jl} - \delta_{il} \delta_{jk}) = \sum_{k \neq l} R_{kllk}.\end{aligned}$$

Define $R_0(X, Y)Z := \frac{1}{2}(\Delta + \delta)(\langle Y, Z \rangle X - \langle X, Z \rangle Y)$ and $D := R - R_0$. Since D and R have the same symmetries we have from (7), (8), (9) in [2] for unit vectors in M_p :

$$|\langle D(X, Y)Y, U \rangle| \leq 2^{-1/2}(\Delta - \delta), \quad (\leq \frac{1}{2}(\Delta - \delta) \text{ if } X \perp U) \quad (5)$$

$$\text{If } Z \perp X, Y \text{ then } |\langle D(X, Y)Z, U \rangle| \leq \frac{2}{3}(\Delta - \delta) \quad (6)$$

$$\|D\| = \max_{|X|=|Y|=|Z|=|U|=1} |\langle D(X, Y)Z, U \rangle| \leq (34/36)^{1/2}(\Delta - \delta). \quad (7)$$

Remark. In forthcoming papers on the differentiable pinching problem Sugimoto and Shiohama have used $\|D\| \leq k$ (with normalization $\Delta + \delta = 2$) as a pinching condition. $\|D\| \leq k$ clearly implies for the sectional curvatures $1 - k \leq K \leq 1 + k$. The converse is not true since for the complex projective space $\|D\| = \frac{4}{3}k$. However $1 - k \leq K \leq 1 + k$ and (7) imply $\|D\| \leq (34/9)^{1/2} k$.

We rewrite (4) as

$$\langle \varrho \omega, \omega \rangle = \Delta + \delta + \frac{1}{2} \sum' D_{klji} \omega_{ij} \omega_{kl} \quad (8)$$

and apply Schwarz' inequality (note $|\omega| = 1$):

$$|\frac{1}{2} \sum' D_{klji} \omega_{ij} \omega_{kl}| \leq (\sum' D_{klji}^2)^{1/2}. \quad (9)$$

(Schwarz' inequality can be applied in various ways to (8) leading to different expressions for the []-bracket in (2); in our computations they were all of the order $n^{3/2}$ or worse. If (2) is a poor estimate the loss probably occurs in (9) since the following estimates seem fairly sharp to us.)

$$\sum' D_{klji}^2 = \sum_{k, l=j, i} D_{klji}^2 + \sum_{k, l=i, j} D_{klji}^2 + \sum_{\substack{k, l, i, j \\ l \neq i, j}} D_{klji}^2 \quad (10)$$

We have from (5) with l, i fixed and $a_k := D_{kjjl} (\sum_k D_{kjjl}^2)^{-1/2}$

$$2^{-1/2}(\Delta - \delta) \geq \left| \sum_k a_k D_{kjjl} \right| = \left(\sum_k D_{kjjl}^2 \right)^{1/2}. \quad (11)$$

If $l \neq i, j$ we have from (6) with $a_k := D_{klji} (\sum_k D_{klji}^2)^{-1/2}$

$$\frac{2}{3}(\Delta - \delta) \geq \left| \sum_k a_k D_{klji} \right| = \left(\sum_k D_{klji}^2 \right)^{1/2}. \quad (12)$$

Insert (11) and (12) in (10) to get

$$\sum' D_{klji}^2 \leq \sum_{j \neq i} (\Delta - \delta)^2 + \sum_{l \neq i \neq j \neq l} \frac{4}{9} (\Delta - \delta)^2 = \frac{4}{9} (\Delta - \delta)^2 n(n-1)(n+\frac{1}{4}). \quad (13)$$

(8), (9) and (13) prove (2).

Remark. The method can also be used to improve Berger's estimate [1] for the Eulercharacteristic:

$$\begin{aligned} \chi(M^{2m}) &= \frac{(-1)^m}{2^{3m} \pi^m m!} \int_M (\varepsilon_{i_1 \dots i_{2m}} \cdot \varepsilon_{j_1 \dots j_{2m}} \cdot R_{i_1 i_2 j_1 j_2} \cdots R_{i_{2m-1} i_{2m} j_{2m-1} j_{2m}}) dV \\ &\leq 2^{-m} (2m)! (\Delta/\delta)^m. \end{aligned}$$

Berger estimates the integrand by $((2m)!)^2 \Delta^m$. We use first $m \cdot \prod_{i=1}^m a_i \leq \sum |a_i|^m \leq \max |a_i|^{m-2} \sum a_i^2$, then Berger's $|R_{klij}| \leq \frac{1}{2} (\Delta - \delta)$, $|R_{klji}| \leq \frac{2}{3} (\Delta - \delta)$ —see (5), (6)—and the analogues of (11), (12) for R instead of D to estimate the integrand by

$$((2m-2)!)^2 \Delta^m 2 \cdot 2m(2m-1) \left[1 + \left(1 - \frac{\delta}{\Delta} \right)^m \left(\left(\frac{1}{4}\right)^m + (m-1) \left(\frac{4}{9}\right)^m \right) \right].$$

We obtain ($m \geq 3$)

$$\chi(M^{2m}) \leq 2.4 \cdot 2^{-m} (2m-2)! (\Delta/\delta)^m.$$

In Dimension 4 Chern's coordinate choice [1] simplifies the integrand to $32(R_{1212}R_{3434} + R_{1313}R_{2424} + R_{1414}R_{2323} + R_{1234}^2 + R_{2314}^2 + R_{3124}^2)$ which Berger estimates by $32(3\Delta'^2 + \frac{8}{9}(\Delta' - \delta')^2)$. Here Δ' and δ' are minimum and maximum at each point. However $R_{1212} = \delta'$ in Chern's coordinates. This improves the estimate to $32(\Delta'\delta' + 2\Delta'^2 + \frac{8}{9}(\Delta' - \delta')^2) \leq 32 \cdot 3\Delta'^2$ and gives $\chi(M^4) \leq (\Delta/\delta)^2$ instead of $\leq (\Delta/\delta)^2 + \frac{8}{27}((\Delta/\delta) - 1)^2$. The same estimate improves known lower bounds for the volume in terms of the second Betti number:

$$2 + b_2 = \chi(M^4) \leq (4\pi^2)^{-1} \cdot 3\Delta^2 \cdot \text{vol}(M^4).$$
