## Semi-continuity of the face-function for a convex set

LARRY Q. EIFLER

### Introduction

Throughout this paper, let  $K$  be a compact convex subset of a locally convex topological vector space  $E$ . Given  $x \in K$ , set  $F(x) = \text{cl} \{y \in K : [y, x + \varepsilon(x - y)] \subseteq K$  for some  $\varepsilon > 0\}$ . We call  $F$  the face-function on  $K$  since  $F(x)$  is the smallest closed face of  $K$  containing  $x$  if  $F(x)$  is finite dimensional. If  $f:K \rightarrow \mathbf{R}$  is continuous, we define the lower envelope  $f_e$  of  $f$  by  $f_e = \sup \{g : g \text{ is a continuous affine function on } K \text{ satisfying } g \leq f\}$ . Following Klee and Martin [3], set  $K_e = \{x \in K : f_e \text{ is continuous at } x\}$  for each continuous function  $f:K \rightarrow \mathbf{R}$  and set  $K_l = \{x \in K : F \text{ is lower semi-continuous at } x\}$ . Klee and Martin proved that  $K_e \subseteq K_l$  in general and that  $K = K_e = K_l$  if  $K$  is 2-dimensional. They left open whether  $K_e = K_l$ . We show that  $K_e = K_l$  if  $K$  is finite dimensional and produce an infinite dimensional example where  $K = K_l \neq K_e$ .

### Lower semi-continuity of $F$

Let  $x \rightarrow F(x)$  be the face-function on  $K$  defined above. We say that  $F$  is lower semi-continuous at  $x$  if for each  $y \in F(x)$  and for each neighborhood  $U$  of  $y$ ,  $\{z \in K : F(z) \text{ meets } U\}$  is a neighborhood of  $x$ . Note that  $F(x)$  is a compact convex subset  $K$  for each  $x \in K$ . If  $F$  is lower semi-continuous on  $K$ , then the set of extreme points  $ex(K)$  of  $K$  is closed. If  $ex(K)$  is closed and if  $K$  is 2 or 3-dimensional, then Clauzing and Magerl [1] have shown that  $K_e = K$  and so  $K_l = K$ .

Let  $P(K)$  denote the space of Radon probability measures on  $K$  and equip  $P(K)$  with the weak\* topology. Given  $\mu \in P(K)$ , there exists a unique point  $r(\mu)$  in  $K$  such that  $\int g d\mu = g(r(\mu))$  for each continuous affine function  $g$  on  $K$ . The map  $r:P(K) \rightarrow K$  is the resultant or barycentric map. If  $x \in K$ , we let  $\delta_x$  denote the point mass measure at  $x$ . The map  $r$  is an open map of  $P(K)$  onto  $K$  if and only if  $K = K_e$ . See [2 or 5]. We say that  $r$  is open at  $\mu \in P(K)$  if for each neighborhood  $U$  of  $\mu$  in  $P(K)$ ,  $r(U) = \{r(\nu) : \nu \in U\}$  is a neighborhood of  $r(\mu)$ . We say that  $r$  is  $\lambda$ -open at  $\mu \in P(K)$  where  $0 < \lambda < 1$  if for each neighborhood  $U$  of  $\mu$

in  $P(K)$ ,  $\lambda r(U) + (1 - \lambda)K$  is a neighborhood of  $r(\mu)$ . We first establish criteria for determining when  $r$  is open at  $\mu$ . These results are of interest aside from their application to the study of the lower semi-continuity of the face-function.

**LEMMA 1.** *Let  $\mu \in P(K)$ . Then  $r$  is open at  $\mu$  if  $r$  is  $\lambda$ -open at  $\mu$  for some  $0 < \lambda < 1$ .*

*Proof.* Assume that  $r$  is  $\lambda$ -open at  $\mu$ . Set  $x = r(\mu)$ . If  $x_\alpha \rightarrow x$ , then there exist  $\mu_\alpha \rightarrow \mu$  and  $y_\alpha \in K$  such that  $\lambda r(\mu_\alpha) + (1 - \lambda)y_\alpha = x_\alpha$ . But  $y_\alpha \rightarrow x$ . Hence, there exist  $\nu_\alpha \rightarrow \mu$  and  $z_\alpha \in K$  such that  $\lambda r(\nu_\alpha) + (1 - \lambda)z_\alpha = y_\alpha$ . Thus,

$$x_\alpha = \lambda(2 - \lambda) \left\{ r \left( \frac{\mu_\alpha}{2 - \lambda} + \frac{(1 - \lambda)\nu_\alpha}{2 - \lambda} \right) \right\} + (1 - \lambda)^2 z_\alpha.$$

One obtains that  $r$  is  $\lambda(2 - \lambda)$ -open at  $\mu$ . Hence,  $r$  is  $\rho$ -open at  $\mu$  for each  $0 < \rho < 1$ . This implies that  $r$  is open at  $\mu$ .

**LEMMA 2.** *Let  $x \in K$ . The following are equivalent.*

- (1)  *$r$  is open at  $\mu$  if  $r(\mu) = x$  and*
- (2)  *$r$  is open at  $\mu$  if  $r(\mu) = x$  and if  $\mu$  is supported by 2 points.*

*Proof.* We only need to show  $(2 \Rightarrow 1)$ . Let  $U$  be a neighborhood of  $\mu$  where  $r(\mu) = x$  and  $\mu$  is supported by  $n$  points. We show that  $r(U)$  is a neighborhood of  $x$  by induction on  $n$ . The result holds for  $n = 2$ . So assume the result holds for  $n \leq m$ . Fix  $\mu \in P(K)$  such that  $r(\mu) = x$  and  $\mu$  is supported by  $\{x_1, \dots, x_{m+1}\}$ . Let  $x = \sum_{i=1}^{m+1} \lambda_i x_i$ . We assume each  $\lambda_i > 0$ . Set  $y_k = (\lambda_k x_k + \lambda_{k+1} x_{k+1}) / (\lambda_k + \lambda_{k+1})$  and set  $\mu_k = \sum_{i=1}^{k-1} \lambda_i \delta_{x_i} + (\lambda_k + \lambda_{k+1}) \delta_{y_k} + \sum_{i>k}^{m+1} \lambda_i \delta_{x_i}$ . Suppose  $x_\alpha \rightarrow x$ . Then there exist  $\mu_k^\alpha \rightarrow \mu_k$  such that  $r(\mu_k^\alpha) = x_\alpha$ . Set  $\nu_\alpha = \sum_{k=1}^{m+1} (1/m + 1) \mu_k^\alpha$ . Then  $r(\nu_\alpha) = x_\alpha$ . Since  $\nu_\alpha \rightarrow \sum_{k=1}^{m+1} (1/m + 1) \mu_k$ , we have  $\lim_\alpha \sup \nu_\alpha(V) \geq (m/m + 1) \lambda_k$  if  $V$  is an open set containing  $x_k$ . Thus, there exist  $\mu_\alpha \rightarrow \mu$  and  $z_\alpha \in K$  such that  $(m/m + 1)r(\mu_\alpha) + (1/m + 1)z_\alpha = x_\alpha$ . Hence,  $r$  is open at  $\mu$  by Lemma 1. By approximating measures by measures with finite support, we see that  $r$  is open at  $\mu$  if  $r(\mu) = x$ .

**THEOREM.** *Let  $x \in K$ . The following are equivalent.*

- (1)  *$f_e$  is continuous at  $x$  for each  $f \in C_R(K)$*
- (2)  *$r$  is open at  $\mu$  if  $r(\mu) = x$*
- (3)  *$r$  is open at  $\mu$  if  $r(\mu) = x$  and if  $\mu$  is supported by 2 points.*

*Proof.* The implication  $(1 \Rightarrow 2)$  follows from Proposition 3.1 in Phelps [4, p.

21]. The implication (2)  $\Rightarrow$  (1) follows from the separation form of the Hahn–Banach theorem and taking limits in the hyperspace of  $P(K)$ . See [2] for details. The implication (2  $\Leftrightarrow$  3) is simply Lemma 2.

**COROLLARY.** *Assume  $K$  is finite dimensional. Then  $K_e = K_l$ .*

*Proof.* The inclusion  $K_e \subseteq K_l$  was established in [3]. Let  $x \in K_l$ . Suppose  $\mu \in P(K)$  such that  $\mu$  is supported by  $\{y, z\}$  and  $r(\mu) = x$ . We only need to show that  $r$  is  $\frac{1}{2}$ -open at  $\mu$  by Lemma 1 and the above theorem. Set  $x = \lambda y + (1 - \lambda)z$  where  $0 \leq \lambda \leq 1$ . We may assume  $y \neq z$  and  $0 < \lambda < 1$ . Let  $U$  be a neighborhood of  $\mu$  in  $P(K)$ . Set  $\Omega = \frac{1}{2}r(U) + \frac{1}{2}K$ . Assume  $\Omega$  is not a neighborhood of  $x$ . Then there exist  $x_n \rightarrow x$  such that  $x_n \notin \Omega$  and  $\dim F(x_n) = q$  where  $q$  is least possible. By taking subsequences, we may assume that there exist  $y_n, z_n \in F(x_n)$  such that  $y_n \rightarrow y$  and  $z_n \rightarrow z$  since  $\limsup F(x_n) \supseteq F(x) \supseteq \{y, z\}$ . Set  $w_n = \lambda y_n + (1 - \lambda)z_n$ . We may assume  $w_n \neq x_n$ . Set  $\varepsilon_n = \max \{\varepsilon : x_n + \varepsilon(w_n - x_n) \in K\}$ . Then  $\dim F(x_n + \varepsilon_n(w_n - x_n)) < \dim F(x_n) = q$ . But,  $w_n \in r(U)$  for  $n$  large. If  $\varepsilon_n \geq 1$  and if  $w_n \in r(U)$ , then

$$\frac{\varepsilon_n}{1 + \varepsilon_n} w_n + \frac{1}{1 + \varepsilon_n} \{x_n + \varepsilon_n(w_n - x_n)\} = x_n \in \Omega.$$

Hence,  $\varepsilon_n < 1$  for  $n$  large. Thus,  $x_n + \varepsilon_n(w_n - x_n) \rightarrow x$  and  $x_n + \varepsilon_n(w_n - x_n) \in \Omega$  which is impossible by the minimality of  $q$ .

*Example 1.* Let  $K$  be the convex hull of  $\{(e^{i\theta}, \pm 1) : 0 \leq \theta \leq \pi\} \cup \{(1, \pm i)\}$  in  $\mathbf{C}^2$ . Then  $K$  is 4-dimensional and  $ex(K)$  is closed. The face-function is not lower semi-continuous at  $(1, 0)$  since  $F(1, 0)$  is a square and  $F(e^{i\theta}, 0)$  is an interval if  $0 < \theta \leq \pi$ .

*Example 2.* Let  $X = \{0, 1, \frac{1}{2}, \frac{1}{3}, \dots\}$  and equip  $X$  with the usual metric from  $\mathbf{R}$ . Let  $K$  denote the closed unit ball in the space of real Radon measures on  $X$ , i.e., the dual of  $C_{\mathbf{R}}(X)$ . Equip  $K$  with the weak\* topology. Then  $K$  is a compact convex set. Given  $\mu \in K$ , set  $\|\mu\| = \mu^+(X) + \mu^-(X)$ . If  $\|\mu\| < 1$ , then  $F(\mu) = K$ . If  $\|\mu\| = 1$ , then  $F(\mu)$  is the closed convex hull of  $\{sgn(\mu(x)) \cdot \delta_x : x \in X\}$ . One easily checks that the face-function is lower semi-continuous on  $K$  and so  $K = K_l$ . The zero measure 0 is not in  $K_e$  by criterion (2) in the theorem since  $\frac{1}{2}[\delta_1 + (-1)\delta_1] = 0$  and  $\frac{1}{2}[\delta_{1/n} + (-1)\delta_{1/(n+1)}] \rightarrow 0$ .
