Arithmetic properties of $\varphi(n)/\lambda(n)$ and the structure of the multiplicative group modulo n

William D. Banks, Florian Luca and Igor E. Shparlinski

Abstract. For a positive integer n , we let $\varphi(n)$ and $\lambda(n)$ denote the Euler function and the Carmichael function, respectively. We define $\xi(n)$ as the ratio $\varphi(n)/\lambda(n)$ and study various arithmetic properties of $\xi(n)$.

Mathematics Subject Classification (2000). 11A25.

Keywords. Euler function, Carmichael function.

1. Introduction and notation

Let $\varphi(n)$ denote the *Euler function*, which is defined as usual by

$$\varphi(n) = \#(\mathbb{Z}/n\mathbb{Z})^\times = \prod_{p^v \parallel n} p^{v-1}(p-1), \quad n \geq 1.$$

The *Carmichael function* $\lambda(n)$ is defined for all $n \geq 1$ as the largest order of any element in the multiplicative group $(\mathbb{Z}/n\mathbb{Z})^\times$. More explicitly, for any prime power p^v , one has

$$\lambda(p^v) = \begin{cases} p^{v-1}(p-1) & \text{if } p \geq 3 \text{ or } v \leq 2, \\ 2^{v-2} & \text{if } p = 2 \text{ and } v \geq 3, \end{cases}$$

and for an arbitrary integer $n \geq 2$,

$$\lambda(n) = \text{lcm}(\lambda(p_1^{v_1}), \dots, \lambda(p_k^{v_k})),$$

where $n = p_1^{v_1} \dots p_k^{v_k}$ is the prime factorization of n . Clearly, $\lambda(1) = 1$.

Despite their many similarities, the functions $\varphi(n)$ and $\lambda(n)$ often exhibit remarkable differences in their arithmetic behavior, and a vast number of results about the growth rate and various arithmetical properties of $\varphi(n)$ and $\lambda(n)$ have been obtained; see for example [4], [5], [7], [8], [9], [11], [15]. In this paper, we consider the

arithmetical function defined by

$$\xi(n) = \frac{\varphi(n)}{\lambda(n)}, \quad n \geq 1,$$

and we study some of its arithmetic properties.

In particular, letting $P(k)$ denote the largest prime factor of a positive integer k (with the convention that $P(1) = 1$), we study the behavior of $P(\xi(n))$. Our results imply that typically $\xi(n)$ is much “smoother” than a random integer k of the same size. To make this comparison, it is useful to recall that Theorem 2 of [9] implies that the estimate

$$\xi(n) = \exp(\log_2 n \log_3 n + C \log_2 n + o(\log_2 n)) \quad (1)$$

holds on a set of positive integers n of asymptotic density 1 with some absolute constant $C > 0$. Here, and in the sequel, for a real number $z > 0$ and a natural number ℓ , we write $\log_\ell z$ for the recursively defined function given by $\log_1 z = \max\{\log z, 1\}$, where $\log z$ denotes the natural logarithm of z , and $\log_\ell z = \max\{\log(\log_{\ell-1} z), 1\}$ for $\ell > 1$. When $\ell = 1$, we omit the subscript (however, we still assume that all the logarithms that appear below are at least 1). Of course, when z is sufficiently large, then $\log_\ell z$ is nothing more than the ℓ -fold composition of the natural logarithm evaluated at z .

We also use $\Omega(n)$ and $\omega(n)$ with their usual meanings: $\Omega(n)$ denotes the total number of prime divisors of $n > 1$ counted with multiplicity, while $\omega(n)$ is the number of distinct prime factors of $n > 1$; as usual, we put $\Omega(1) = \omega(1) = 0$. In this paper, we also study the functions $\Omega(\xi(n))$ and $\omega(\xi(n))$.

Observe that a prime p divides $\xi(n)$ if and only if the p -Sylow subgroup of the group $(\mathbb{Z}/n\mathbb{Z})^\times$ is not cyclic. Thus, $P(\xi(n))$ and $\omega(\xi(n))$ can be viewed as measures of “non-cyclicity” of this group. In particular, $\omega(\xi(n))$ is the number of non-cyclic Sylow subgroups of $(\mathbb{Z}/n\mathbb{Z})^\times$.

We also remark that any prime $p \mid \xi(n)$ has that property that $p^2 \mid \varphi(n)$. Thus, while studying the prime factors of $\xi(n)$, one is naturally lead to an associated question concerning the difference $\Omega(\varphi(n)) - \omega(\varphi(n))$, a question that we address here as well.

As usual, for a large number x , $\pi(x)$ denotes the number of primes $p \leq x$, and for positive integers a, k with $\gcd(a, k) = 1$, $\pi(x; k, a)$ denotes the number of primes $p \leq x$ with $p \equiv a \pmod{k}$.

We use the Vinogradov symbols \gg, \ll, \asymp as well as the Landau symbols O and o with their usual meanings. The implied constants in the symbols O, \gg, \ll and \asymp are always absolute unless indicated otherwise.

Finally, we say that a certain property holds for “almost all” n if it holds for all $n \leq x$ with at most $o(x)$ exceptions, as $x \rightarrow \infty$.

Acknowledgements. The authors wish to thank Carl Pomerance for suggesting the statement of Theorem 9 and for some useful references. During the preparation of this paper, W. B. was supported in part by NSF grant DMS-0070628, F. L. was supported in part by grants SEP-CONACYT 37259-E and 37260-E, and I. S. was supported in part by ARC grant DP0211459.

2. Distribution of $P(\xi(n))$, $\omega(\xi(n))$ and $\Omega(\xi(n))$

In what follows, let us call a real-valued function $\varepsilon(x)$ *admissible* if

- $\varepsilon(x)$ is a decreasing function, with limit 0 as $x \rightarrow \infty$;
- $\varepsilon(x) \log_2 x$ is an increasing function, tending to ∞ as $x \rightarrow \infty$.

We begin with the following statement, which may be of independent interest.

Lemma 1. *For any admissible function $\varepsilon(x)$ and any prime $q \leq \varepsilon(x) \log_2 x$, every positive integer $n \leq x$ has at least $(\log_2 n)/2q$ distinct prime factors $p \equiv 1 \pmod{q}$, with at most $o(x)$ exceptions.*

Proof. Let $\omega(n, q)$ denote the number of distinct prime factors p of n such that $p \equiv 1 \pmod{q}$. For any real number $y \geq 1$ and integer $a \geq 1$, put

$$S(y, a) = \sum_{\substack{p \leq y \\ p \equiv 1 \pmod{a}}} \frac{1}{p}. \quad (2)$$

It is known (see Theorem 1 in [18] or Lemma 6.3 in [17]) that

$$S(y, a) = \frac{\log_2 y}{\varphi(a)} + O(1). \quad (3)$$

In particular, the estimate

$$S(n, q) = \frac{\log_2 n}{q-1} + O(1) \gg \varepsilon(x)^{-1}$$

holds for all q in the stated range and all $n > x^{1/2}$, once x is sufficiently large. By the classical result of Turán [20], we also have that the estimate

$$\omega(n, q) = S(n, q) + O(S(n, q)^{2/3})$$

holds for all n in the interval $x^{1/2} < n \leq x$, with at most

$$O(xS(n, q)^{-1/6}) = O(x\varepsilon(x)^{1/6}) = o(x)$$

possible exceptions, and the result now follows. \square

Lemma 2. For real numbers $x \geq y > 1$ let

$$\Xi(x, y) = \#\{n \leq x : P(\xi(n)) > y\}.$$

Then,

$$\Xi(x, y) \ll \frac{x(\log_2 x)^2}{y \log y}.$$

Proof. If a prime q divides $\xi(n)$, then clearly $q^2 \mid \varphi(n)$. The upper bound

$$\#\{n \leq x : \varphi(n) \equiv 0 \pmod{q^2}\} \ll \frac{x(\log_2 x)^2}{q^2}$$

is a special partial case of Lemma 2 of [5] (see also the proof of Theorem 7.1 in [4]). In particular,

$$\#\{n \leq x : P(\xi(n)) = q\} \ll \frac{x(\log_2 x)^2}{q^2}. \quad (4)$$

It now follows that

$$\Xi(x, y) = \sum_{y < q \leq x} \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1 \ll \sum_{y < q \leq x} \frac{x(\log_2 x)^2}{q^2}.$$

Using Abel summation, we estimate

$$\sum_{y < q \leq x} \frac{1}{q^2} = \frac{\pi(x)}{x^2} - \frac{\pi(y)}{y^2} + 2 \int_y^x \frac{\pi(t)}{t^3} dt \ll \frac{1}{x \log x} + \int_y^x \frac{1}{t^2 \log t} dt \ll \frac{1}{y \log y},$$

and the lemma follows. \square

Theorem 1. If $\varepsilon(x)$ is any admissible function, then the inequalities

$$\varepsilon(n) \log_2 n \leq P(\xi(n)) \leq \frac{(\log_2 n)^2}{\varepsilon(n) \log_3 n}$$

hold for almost all positive integers n .

Proof. By the Prime Number Theorem, for all sufficiently large real numbers x there exists a prime q in the interval:

$$\varepsilon(x) \log_2 x < q \leq 2 \varepsilon(x) \log_2 x.$$

If n is an integer with two prime factors $p_1 \equiv p_2 \equiv 1 \pmod{q}$, then $q \mid \xi(n)$. By Lemma 1, we derive that

$$\sum_{\substack{x^{1/2} < n \leq x \\ P(\xi(n)) \geq \varepsilon(n) \log_2 n}} 1 \geq \sum_{\substack{x^{1/2} < n \leq x \\ P(\xi(n)) \geq q}} 1 \geq \sum_{\substack{x^{1/2} < n \leq x \\ \omega(n, q) \geq 2}} 1 = x + o(x).$$

This proves the lower bound. The upper bound is a direct application of Lemma 2. \square

We remark that the upper bound of Theorem 1 improves the corollary to Theorem 2 in [9].

Theorem 2. *As $x \rightarrow \infty$, we have*

$$(1 + o(1)) x \log_3 x \leq \sum_{n \leq x} \log P(\xi(n)) \leq (2 + o(1)) x \log_3 x.$$

Proof. The above lower bound follows from the lower bound from Theorem 1. For the upper bound above, we write

$$\sum_{n \leq x} \log P(\xi(n)) = \sum_{q \leq x} \log q \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1.$$

For $q \leq y$, we trivially have

$$\sum_{q \leq y} \log q \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1 \leq \log y \sum_{q \leq y} \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1 \leq \log y \sum_{n \leq x} 1 \leq x \log y,$$

while for $q > y$, we have, by (4):

$$\sum_{y < q \leq x} \log q \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1 \ll x (\log_2 x)^2 \sum_{y < q \leq x} \frac{\log q}{q^2} \ll xy^{-1} (\log_2 x)^2,$$

where we have used Abel summation to estimate

$$\begin{aligned} \sum_{y < q \leq x} \frac{\log q}{q^2} &= \pi(x) \frac{\log x}{x^2} - \pi(y) \frac{\log y}{y^2} - \int_y^x \pi(t) \left(\frac{1}{t^3} - \frac{2 \log t}{t^3} \right) dt \\ &\ll x^{-1} + \int_y^x t^{-2} dt \ll y^{-1}. \end{aligned}$$

Setting $y = (\log_2 x)^2$, we obtain the desired upper bound. \square

Theorem 3. *As $x \rightarrow \infty$, we have*

$$\sum_{n \leq x} P(\xi(n)) \asymp x (\log_2 x)^3.$$

Proof. Let $y = (\log_2 x)^3$, $z = \exp((\log x)^{1/2})$ and $w = \exp((\log x)^{2/3})$. We also put $v = z^6$. In what follows, x is taken to be arbitrarily large.

Taking $A = 5/2$, $\varepsilon = 1/2$, and $\delta = 1/15$ in the statement of Theorem 2.1 of [1], we see that there exists an absolute constant $D \geq 0$ and a set \mathcal{D} of cardinality $\#\mathcal{D} \leq D$, with $\min\{m : m \in \mathcal{D}\} \geq \log v = 6(\log x)^{1/2}$, such that the inequality

$$\pi(t; d, 1) \geq \frac{\pi(t)}{2\varphi(d)} \quad (5)$$

holds for all positive reals t provided that $1 \leq d \leq \min\{tv^{-2/3}, z^2\}$ and that d is not divisible by any element of \mathcal{D} . Note that if x is sufficiently large and $t \geq w$, then $tv^{-2/3} \geq wv^{-2/3} \geq z^2$.

Letting \mathcal{Q} denote the set of primes $q \in [y, z] \setminus \mathcal{D}$, we therefore see that the lower bound (5) holds for all $t \in [w, x]$ and all integers $d \in [1, z^2]$ whose prime factors all lie in \mathcal{Q} . Together with the Brun–Titchmarsh theorem (see for example Theorem 3.7 in Chapter 3 of [12]), we conclude that

$$\pi(t; d, 1) \asymp \frac{\pi(t)}{\varphi(d)}$$

holds uniformly for all $t \in [w, x]$ and all integers d of the form $d = q$ or $d = q_1 q_2$ composed of one or two (not necessarily distinct) primes from \mathcal{Q} . Moreover, for any sufficiently large constant $\gamma > 1$, we also have

$$\pi(t; d, 1) - \pi(t/\gamma; d, 1) \asymp \frac{\pi(t)}{\varphi(d)} \quad (6)$$

under the same conditions.

We now let

$$k = \left\lceil \frac{\log w}{\log \gamma} \right\rceil \quad \text{and} \quad K = \left\lfloor \frac{\log x}{2 \log \gamma} \right\rfloor - 1.$$

For any prime $q \in \mathcal{Q}$, we have, by (6):

$$\sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q}}} \frac{1}{p} \geq \sum_{j=k}^K \frac{\pi(\gamma^{j+1}; d, 1) - \pi(\gamma^j; d, 1)}{\gamma^{j+1}} \gg \frac{1}{q} \sum_{j=k}^K \frac{1}{j} \gg \frac{\log_2 x}{q}.$$

On the other hand, the upper bound (3.1) in [7] (see also Lemma 1 of [5]) provides an upper bound of the same size as the above lower bound. Consequently,

$$\sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q}}} \frac{1}{p} \asymp \frac{\log_2 x}{q}. \quad (7)$$

We now fix a prime number q in \mathcal{Q} . We denote by $N(x, q)$ the number of integers $n \leq x$ for which there exists a unique representation of the form $n = p_1 p_2 m$ for some integer m and two primes $w < p_1 < p_2 \leq x^{1/2}$ with $p_1 \equiv p_2 \equiv 1 \pmod{q}$ and such that q is the only prime in \mathcal{Q} dividing $\gcd(p_1 - 1, p_2 - 1)$. We then have

$$N(x, q) \geq T_0(x, q) - T_1(x, q) - T_2(x, q) - T_3(x, q),$$

where

- $T_0(x, q)$ is the total number of ordered triples (p_1, p_2, m) with primes $w < p_1 < p_2 \leq x^{1/2}$, $p_1 \equiv p_2 \equiv 1 \pmod{q}$, and an integer $m \leq x/p_1 p_2$. Therefore, using (7), we obtain that

$$\begin{aligned} T_0(x, q) &\gg x \sum_{\substack{w < p_1 < p_2 \leq x^{1/2} \\ p_1 \equiv p_2 \equiv 1 \pmod{q}}} \frac{1}{p_1 p_2} \\ &= \frac{x}{2} \left(\sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q}}} \frac{1}{p} \right)^2 - \frac{x}{2} \sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q}}} \frac{1}{p^2} \\ &\gg \frac{x}{2} \left(\frac{\log_2 x}{q} \right)^2 - \frac{x}{2q} \sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q}}} \frac{1}{p} \\ &= \frac{x(\log_2 x)^2}{2q^2} + O\left(\frac{x \log_2 x}{q^2}\right) \gg \frac{x(\log_2 x)^2}{q^2}. \end{aligned}$$

- $T_1(x, q)$ is the number of triples (p_1, p_2, m) as above for which there exists another prime $\ell \in \mathcal{Q}$, $\ell \neq q$, such that $p_1 \equiv p_2 \equiv 1 \pmod{\ell}$. Then, by (7), we have that

$$\begin{aligned} T_1(x, q) &\ll x \sum_{\substack{\ell \in \mathcal{Q} \\ \ell \neq q}} \sum_{\substack{w < p_1 < p_2 \leq x^{1/2} \\ p_1 \equiv p_2 \equiv 1 \pmod{q\ell}}} \frac{1}{p_1 p_2} \leq x \sum_{\ell \in \mathcal{Q}} \left(\sum_{\substack{w < p \leq x^{1/2} \\ p \equiv 1 \pmod{q\ell}}} \frac{1}{p} \right)^2 \\ &\ll x \sum_{\ell \in \mathcal{Q}} \frac{(\log_2 x)^2}{q^2 \ell^2} \ll \frac{x(\log_2 x)^2}{q^2} \sum_{\ell > y} \frac{1}{\ell^2} \\ &\ll \frac{x(\log_2 x)^2}{q^2 y \log y} = o\left(\frac{x(\log_2 x)^2}{q^2}\right). \end{aligned}$$

- $T_2(x, q)$ is the number of triples (p_1, p_2, m) as above for which there exists another prime p_3 , $w < p_3 \leq x^{1/2}$, which divides m , and for some prime $\ell \in \mathcal{Q}$

(possibly $\ell = q$) one has $p_3 \equiv 1 \pmod{\ell}$, and either $p_1 \equiv 1 \pmod{\ell}$, or $p_2 \equiv 1 \pmod{\ell}$. Therefore, by (7), we see that

$$\begin{aligned}
T_2(x, q) &\ll x \sum_{\ell \in \mathcal{Q}} \sum_{\substack{w < p_1, p_2 \leq x^{1/2} \\ w < p_3 \leq x^{1/2} \\ p_1 \equiv p_2 \equiv 1 \pmod{q} \\ p_3 \equiv p_2 \equiv 1 \pmod{\ell}}} \frac{1}{p_1 p_2 p_3} \\
&\ll x \sum_{\ell \in \mathcal{Q}} \sum_{\substack{w < p_1 \leq x^{1/2} \\ p_1 \equiv 1 \pmod{q}}} \frac{1}{p_1} \sum_{\substack{w < p_2 \leq x^{1/2} \\ p_2 \equiv 1 \pmod{q\ell}}} \frac{1}{p_2} \sum_{\substack{w < p_3 \leq x^{1/2} \\ p_3 \equiv 1 \pmod{\ell}}} \frac{1}{p_3} \\
&\ll x (\log_2 x)^3 \sum_{y \leq \ell \leq z} \frac{1}{q^2 \ell^2} \ll \frac{x (\log_2 x)^3}{q^2 y \log y} = o\left(\frac{x (\log_2 x)^2}{q^2}\right).
\end{aligned}$$

- $T_3(x, q)$ is the number of triples (p_1, p_2, m) as above for which there exists another triple (r_1, r_2, k) with primes $w \leq r_1 < r_2 \leq x^{1/2}$ such that $r_1 \equiv r_2 \equiv 1 \pmod{\ell}$ for some $\ell \in \mathcal{Q}$, and $p_1 p_2 m = r_1 r_2 k$. Applying (7) once again, we obtain that

$$\begin{aligned}
T_3(x, q) &\ll x \sum_{\ell \in \mathcal{Q}} \sum_{\substack{w < p_1 < p_2 \leq x^{1/2} \\ p_1 \equiv p_2 \equiv 1 \pmod{q}}} \frac{1}{p_1 p_2} \sum_{\substack{w < r_1 < r_2 \leq x^{1/2} \\ r_1 \equiv r_2 \equiv 1 \pmod{\ell}}} \frac{1}{r_1 r_2} \\
&\ll x (\log_2 x)^4 \sum_{y \leq \ell \leq z} \frac{1}{q^2 \ell^2} \ll \frac{x (\log_2 x)^4}{q^2 y \log y} = o\left(\frac{x (\log_2 x)^2}{q^2}\right).
\end{aligned}$$

Consequently, we have

$$N(x, q) \geq T_0(x, q) - T_1(x, q) - T_2(x, q) - T_3(x, q) \gg \frac{x (\log_2 x)^2}{q^2}.$$

We note that $P(\xi(n)) \geq q$ for all $n \in N(x, q)$ and that the sets $N(x, q)$ are disjoint for different choices of $q \in \mathcal{Q}$. Thus,

$$\begin{aligned}
\sum_{n \leq x} P(\xi(n)) &\gg \sum_{q \in \mathcal{Q}} q \#N(x, q) \gg x (\log_2 x)^2 \sum_{q \in \mathcal{Q}} \frac{1}{q} \\
&\geq x (\log_2 x)^2 \left(\sum_{y \leq q \leq z} \frac{1}{q} - \frac{D}{6 (\log x)^{1/2}} \right) \\
&\gg x (\log_2 x)^2 (\log_2 z - \log_2 y + o(1)) \gg x (\log_2 x)^3.
\end{aligned}$$

To prove the upper bound, we simply use (4) to derive that

$$\sum_{n \leq x} P(\xi(n)) \leq \sum_{q \leq x} q \sum_{\substack{n \leq x \\ P(\xi(n))=q}} 1 \ll x(\log_2 x)^2 \sum_{q \leq x} \frac{1}{q} \ll x(\log_2 x)^3.$$

This completes the proof. \square

Concerning the minimal order of $P(\xi(n))$, little need be said; clearly $P(\xi(n)) \geq 1$ for all $n \geq 1$, and equality holds if and only if $n = 2, 4, p^\nu$ or $2p^\nu$ for some odd prime p and $\nu \geq 1$. As for the maximal order, we have the following:

Theorem 4. *The inequality*

$$P(\xi(n)) \leq \frac{(3n+1)^{1/2} - 2}{6}$$

holds for all $n \geq 276$, and the inequality

$$P(\xi(n)) \gg n^{0.3335}$$

holds for infinitely many n .

Proof. For n in the range $276 \leq n \leq 579$, the upper bound can be verified case by case; hence, we assume that $n \geq 580$ in what follows. Without loss of generality, we may further assume that $q = P(\xi(n)) > 3$, since

$$3 \leq \frac{(3n+1)^{1/2} - 2}{6} \quad \text{holds for all } n \geq 133.$$

If $P(\xi(n)) = q$, then either n has a prime divisor $p \equiv 1 \pmod{q}$ and $q^2 p \mid n$, or n has two distinct prime divisors $p_1 \equiv p_2 \equiv 1 \pmod{q}$. In the first case, we see that

$$q < (q^2 p/2)^{1/3} \leq (n/2)^{1/3} \leq \frac{(3n+1)^{1/2} - 2}{6},$$

the last inequality being valid for all $n \geq 580$. In the second case, suppose $p_1 = aq + 1$ and $p_2 = bq + 1$, where $a < b$ are distinct even integers. Now if $2q + 1$ is prime, then $4q + 1$ is divisible by 3; thus, we must have $a \geq 2, b \geq 6$. Then

$$(2q+1)(6q+1) \leq (aq+1)(bq+1) = p_1 p_2 \leq n,$$

and we obtain the stated upper bound.

To establish the lower bound, we recall the result of Fouvry [10], which asserts that for all large x , the set \mathcal{Q} of primes p in the interval $x^{1/2} \leq p \leq x$ and satisfying $P(p-1) \gg p^{0.667}$ is of cardinality $\#\mathcal{Q} \gg x/\log x$. We also recall that, by Brun's

method (see Theorem 2.2 in [12]), for any integer m , the number of primes of the form $p = mq + 1 \leq x$ for some other prime q is

$$O\left(\frac{x}{\varphi(m)(\log(x/m))^2}\right) = O\left(\frac{x}{\varphi(m)(\log x)^2}\right)$$

provided that $m < x^{1/2}$. Summing up the above inequalities over all positive integers $m \leq \log_2 x$, we see that

$$\#\{p \leq x : P(p-1) \geq x/\log_2 x\} \ll \frac{x}{\log^2 x} \sum_{m < \log x} \frac{1}{\varphi(m)} \ll \frac{x \log_2 x}{\log^2 x} = o(\mathcal{Q}).$$

Thus, most of the primes p in \mathcal{Q} in the interval have $q = P(p-1) < x/\log_2 x$, and therefore there exist two primes $p_1, p_2 \in \mathcal{Q}$ with the same value of $P(p_1-1) = P(p_2-1) = q$. With $n = p_1 p_2$, we see that $P(\xi(n)) \geq q \gg \max\{p_1^{0.667}, p_2^{0.667}\} \gg n^{0.3335}$. \square

As is clear from the proof, the upper bound of Theorem 4 is tight under the prime k -tuple conjecture of Hardy and Littlewood (see, for example, [3]). We also remark that the trivial upper bound $P(\xi(n)) \leq n^{1/2}$ holds for all $n \geq 1$.

Unfortunately, our method of proof for the lower bound of Theorem 4 can not be combined with the more recent results of [2], since the set of primes considered there is too thin.

Theorem 5. *The inequalities*

$$\Omega(\xi(n)) = (1 + o(1)) \log_2 n \log_4 n \quad \text{and} \quad \frac{\log_2 n}{(\log_3 n)^2} \ll \omega(\xi(n)) \ll \log_2 n$$

hold for almost all positive integers n .

Proof. We start with $\Omega(\xi(n))$ and first turn our attention to the upper bound. Let x be a large positive real number, and let \mathcal{A}_1 be the set of all positive integers n in the interval $[x/\log x, x]$. Clearly, \mathcal{A}_1 contains all but $o(x)$ positive integers $n \leq x$. Let \mathcal{A}_2 be the set of those integers $n \in \mathcal{A}_1$ for which $P(\xi(n)) \leq (\log_2 x)^2$; by Theorem 1, \mathcal{A}_2 contains all but $o(x)$ positive integers $n \leq x$. Let $y = (\log_2 x)^2$. For any positive integer m , we write

$$\omega_y(m) = \sum_{\substack{p < y \\ p \mid m}} 1 \quad \text{and} \quad \Omega_y(m) = \sum_{\substack{p < y \\ p^v \parallel m}} v.$$

Thus, the inequality $\Omega(\xi(n)) \leq \Omega_y(\varphi(n))$ holds for all $n \in \mathcal{A}_2$. The argument on page 349 in [8] shows that

$$\sum_{n \leq x} |\Omega_y(\varphi(n)) - \log_2 x \log_2 y|^2 \ll x \log_2 x (\log_2 y)^2. \quad (8)$$

Now let $\varepsilon_1(x) = (\log_2 x)^{-1/3}$, and let \mathcal{B} be the set of those $n \leq x$ such that

$$\Omega_y(\varphi(n)) > (1 + \varepsilon_1(x)) \log_2 x \log_2 y.$$

Using (8), it follows that

$$\#\mathcal{B} \ll \frac{x}{\varepsilon_1(x)^2 \log_2 x} = o(x).$$

The set $\mathcal{A}_3 = \mathcal{A}_2 \setminus \mathcal{B}$ contains all but $o(x)$ positive integers $n \leq x$, and for each $n \in \mathcal{A}_3$ we have

$$\Omega(\xi(n)) \leq \Omega_y(\varphi(n)) \leq (1 + \varepsilon_1(x)) \log_2 x \log_2 y = (1 + o(1)) \log_2 x \log_4 x. \quad (9)$$

Since $n \geq x/\log x$ for all $n \in \mathcal{A}_3$, this shows that

$$\Omega(\xi(n)) \leq (1 + o(1)) \log_2 n \log_4 n$$

for almost all positive integers n .

Next we turn to the lower bound for $\Omega(\xi(n))$. As before, let x be a large real number, and put $\varepsilon_2(x) = (\log_3 x)^{-1/3}$ and $Q = (\log_2 x)^{1/2}$. For natural numbers n and q , we again write $\omega(n, q)$ for the number of prime factors p of n that are congruent to 1 modulo q . For a prime $q \leq Q$ we define the sets

$$\mathcal{C}_q = \left\{ n \leq x : \omega(n, q) \leq (1 - \varepsilon_2(x)) \frac{\log_2 x}{\varphi(q)} \right\},$$

and

$$\mathcal{C} = \bigcup_{q \leq Q} \mathcal{C}_q.$$

We claim that $\#\mathcal{C} = o(x)$ as $x \rightarrow \infty$. Indeed, for a fixed prime $q \leq Q$, by a result of Turán [20] (see also (1.2) of [17]), we have

$$\#\mathcal{C}_q \ll \frac{xq}{\varepsilon_2^2(x) \log_2 x} \ll \frac{x(\log_3 x)^{2/3}}{\log_2 x} q.$$

Therefore,

$$\#\mathcal{C} \leq \sum_{q \leq Q} \#\mathcal{C}_q \ll \frac{x(\log_3 x)^{2/3}}{\log_2 x} \sum_{q \leq (\log_2 x)^{1/2}} q \ll \frac{x}{(\log_3 x)^{1/3}} = o(x).$$

Now let \mathcal{D} be the set of those positive integers $n \leq x$ not lying in \mathcal{C} . Then for each

$n \in \mathcal{D}$, one has

$$\begin{aligned}
\Omega(\xi(n)) &\geq \sum_{q \leq Q} (\omega(n, q) - 1) = \sum_{q \leq Q} \omega(n, q) - \pi(Q) \\
&\geq (1 - \varepsilon_2(x)) \log_2 x \sum_{q \leq Q} \frac{1}{\varphi(q)} - \pi(Q) \\
&\geq (1 - \varepsilon_2(x)) \log_2 x \sum_{q \leq Q} \frac{1}{q} - \pi(Q) \\
&\geq (1 + o(1)) \log_2 x \log_4 x \geq (1 + o(1)) \log_2 n \log_4 n.
\end{aligned}$$

This completes the proof of the normal order of $\Omega(\xi(n))$.

We now turn our attention to $\omega(\xi(n))$ and start with the lower bound. Again, let x be a large positive real number, and let $\varepsilon_3(x)$ be any admissible function. Let q be a prime number and let $v_q(m)$ denote the largest power of q dividing a natural number m . It suffices to show that there exists a constant c_1 such that for all but $o(x)$ positive integers $n \leq x$, the estimate

$$v_q(\xi(n)) \geq \varepsilon_3(x) \log_2 x, \quad (10)$$

holds simultaneously for all primes $q \leq c_1 \log_2 x / \log_3 x$.

Let us define

$$\mathcal{W}_q = \left\{ n \leq x : \omega(n, q) < \frac{\log_2 x}{2\varphi(q)} \right\}.$$

By the result of Turán mentioned above, we have $\#\mathcal{W}_q \ll xq / \log_2 x$; summing up these estimates for all $q \leq (\log_3 x)^{1/2}$, we see that

$$\sum_{q \leq (\log_3 x)^{1/2}} \#\mathcal{W}_q \ll \frac{x}{\log_2 x} \sum_{q \leq (\log_3 x)^{1/2}} q \ll \frac{x \log_3 x}{\log_2 x \log_4 x} = o(x).$$

We also note that for $q \leq (\log_3 x)^{1/2}$, we have

$$\frac{\log_2 x}{2\varphi(q)} \gg \frac{\log_2 x}{(\log_3 x)^{1/2}}$$

which establishes (10) for q in this small range if $\varepsilon_3(x) \leq (\log_3 x)^{-1/2}$, which we now assume.

Next we consider the case in which $q > (\log_3 x)^{1/2}$.

Let us denote by $\omega_y(n)$ the number of prime factors p of n with $p \leq y$. Let \mathcal{N} be the set of integers $x^{1/2} \leq n \leq x$ for which

$$\omega_y(n) = \log_2 y + O((\log_2 y)^{2/3})$$

holds simultaneously for $y = \exp((\log x)^{1/2})$ and for $y = x$. By [20], we have that $\#\mathcal{N} = x + o(x)$.

Let \mathcal{E}_q be the set of $n \in \mathcal{N}$ such that $p^2 \mid n$ for some $p \equiv 1 \pmod{q}$ and let \mathcal{E} be the union of all \mathcal{E}_q for $q > (\log_3 x)^{1/2}$. Clearly,

$$\#\mathcal{E}_q \ll \sum_{p \equiv 1 \pmod{q}} \frac{x}{p^2} \leq \frac{x}{q^2} \sum_{t \geq 1} \frac{1}{t^2} \ll \frac{x}{q^2},$$

and therefore

$$\#\mathcal{E} \leq \sum_{q > (\log_3 x)^{1/2}} \#\mathcal{E}_q \ll x \sum_{q > (\log_3 x)^{1/2}} \frac{1}{q^2} = o\left(\frac{x}{(\log_3 x)^{1/2}}\right) = o(x).$$

For a fixed positive integer k and primes $p_1 \equiv \dots \equiv p_k \equiv 1 \pmod{q}$, let $\mathcal{N}_{k,q}(p_1, \dots, p_k)$ be the set of integers $n \in \mathcal{N} \setminus \mathcal{E}$ such that $n = p_1 \dots p_k m$ holds with some integer m with $\omega(m, q) = 0$.

We first show that if $k \leq 0.5 \log_2 x$, then $\mathcal{N}_{k,q}(p_1, \dots, p_k)$ is empty unless

$$\frac{x}{p_1 \dots p_k} \geq z, \quad (11)$$

where $z = \exp((\log x)^{1/2})$. Indeed, in the opposite case, we see that for $n \in \mathcal{N}_{k,q}(p_1, \dots, p_k)$,

$$\omega(n) \leq k + \omega(m) \leq k + \omega_z(n) \leq 0.5 \log_2 x + O((\log_2 x)^{1/2}),$$

which is impossible because $\omega(n) \sim \log_2 n \sim \log_2 x$ for $n \in \mathcal{N}$.

We now have

$$\#\mathcal{N}_{k,q}(p_1, \dots, p_k) \leq \sum_{\substack{m \leq x/(p_1 \dots p_k) \\ q \nmid \varphi(m)}} 1. \quad (12)$$

It has been shown in the proof of Theorem 4.1 of [7] that there exists an absolute constant $c_2 > 0$ such that the upper bound

$$\sum_{\substack{m \leq t \\ q \nmid \varphi(m)}} 1 \ll t \exp(-c_2 S(t, q))$$

holds uniformly when $\log t > q$, where $S(t, q)$ is given by (2). By Theorem 3.4 of [7], we know that the lower bound

$$S(t, q) \gg \frac{\log_2 t}{q}$$

holds provided that $q < \log t$. Thus, assuming (11), and remarking that $\log z = (\log x)^{1/2} > q$, we derive from (12) that the estimate

$$\#\mathcal{N}_{k,q}(p_1, \dots, p_k) \ll \frac{x}{p_1 \dots p_k} \exp\left(-c_3 \frac{\log_2 x}{q}\right)$$

holds with some absolute constant $c_3 > 0$.

Therefore, the set $\mathcal{N}_{k,q}$ consisting of all integers n in $\mathcal{N} \setminus \mathcal{E}$ that belong to at least one of the sets $\mathcal{N}_{k,q}(p_1, \dots, p_k)$, for fixed k and q , has cardinality at most

$$\begin{aligned} \#\mathcal{N}_{k,q} &= \frac{1}{k!} \sum_{\substack{p_1 < x \\ p_1 \equiv 1 \pmod{q}}} \dots \sum_{\substack{p_k < x \\ p_k \equiv 1 \pmod{q}}} \#\mathcal{N}_{k,q}(p_1, \dots, p_k) \\ &\leq \frac{1}{k!} \sum_{\substack{p_1 < x \\ p_1 \equiv 1 \pmod{q}}} \dots \sum_{\substack{p_k < x \\ p_k \equiv 1 \pmod{q}}} \frac{x}{p_1 \dots p_k} \exp\left(-c_3 \frac{\log_2 x}{q}\right) \\ &\leq \frac{x}{k!} \exp\left(-c_3 \frac{\log_2 x}{q}\right) S(x, q)^k. \end{aligned}$$

Put $K_q = \varepsilon_3(x)(\log_2 x)/q$. Recalling the bound (3) and using the Stirling formula, we obtain

$$\begin{aligned} \sum_{k \leq K_q} \#\mathcal{N}_{k,q} &\ll x \exp\left(-c_3 \frac{\log_2 x}{q}\right) \sum_{k \leq K_q} \frac{(2 \log_2 x)^k}{q^k k!} \\ &\ll x \exp\left(-c_3 \frac{\log_2 x}{q}\right) \sum_{k \leq K_q} \left(\frac{6 \log_2 x}{qk}\right)^k. \end{aligned}$$

Furthermore, we derive

$$\begin{aligned} \sum_{k \leq K_q} \left(\frac{6 \log_2 x}{qk}\right)^k &\ll \sum_{0 \leq i \leq \log K_q} \sum_{K_q e^{-i-1} \leq k \leq K_q e^{-i}} \left(\frac{6e^{i+1} \log_2 x}{qK_q}\right)^k \\ &= \sum_{0 \leq i \leq \log K_q} \sum_{K_q e^{-i-1} \leq k \leq K_q e^{-i}} \left(6\varepsilon_3^{-1}(x)e^{i+1}\right)^k \\ &\ll \sum_{0 \leq i \leq \log K_q} \left(6\varepsilon_3^{-1}(x)e^{i+1}\right)^{K_q e^{-i}} \\ &\ll \exp\left(c_4 K_q \log(\varepsilon_3^{-1}(x))\right) \end{aligned}$$

for some constant c_4 . Therefore, for an appropriate constant c_1 ,

$$\begin{aligned} & \sum_{q \leq c_1 \log_2 x / \log_3 x} \sum_{k \leq K_q} \# \mathcal{N}_{k,q} \\ & \ll x \sum_{q \leq c_1 \log_2 x / \log_3 x} \exp \left(-c_3 \frac{\log_2 x}{q} + c_4 K_q \log (\varepsilon_3^{-1}(x)) \right) \\ & \ll x \sum_{q \leq c_1 \log_2 x / \log_3 x} \exp \left(-0.5c_3 \frac{\log_2 x}{q} \right) = o(x) \end{aligned}$$

provided that x is large enough. Clearly, the inequality (10) implies the desired lower bound on $\omega(\xi(n))$.

We now prove the upper bound on $\omega(\xi(n))$. By (1), we know that the inequality

$$\log(\xi(n)) \ll \log_2 n \log_3 n \quad (13)$$

holds on a set of positive integers n of asymptotic density 1. The upper bound on $\omega(\xi(n))$ claimed by our Theorem 5 follows now from inequality (13) above combined with the classical estimate

$$\omega(\xi(n)) \ll \frac{\log \xi(n)}{\log_2 \xi(n)},$$

which concludes the proof. \square

It is easy to see that Theorem 5 implies that for some constant $c_5 > 0$, the bound

$$\tau(\xi(n)) \geq 2^{\omega(\xi(n))} \gg \exp \left(c_5 \frac{\log_2 n}{(\log_3 n)^2} \right)$$

holds for almost all positive integers n , where, as usual, $\tau(k)$ denotes the number of divisors of an integer $k \geq 1$.

It is also clear that for any positive integer n

$$\omega(\xi(n)) \leq \omega(\varphi(n)) \ll \frac{\log \varphi(n)}{\log_2 \varphi(n)} \ll \frac{\log n}{\log_2 n}$$

and

$$\Omega(\xi(n)) \ll \Omega(\varphi(n)) \ll \log \varphi(n) \ll \log n.$$

Theorem 6. *The inequalities*

$$\Omega(\xi(n)) \gg \log n \quad \text{and} \quad \omega(\xi(n)) \gg \frac{\log n}{\log_2 n}$$

hold for infinitely many positive integers n .

Proof. Let k be a sufficiently large integer, and then let p_1 and p_2 be the first two primes in the arithmetic progression $1 \pmod{2^k}$. By Linnik's Theorem, in the form given by Heath-Brown [13], we know that $\max\{p_1, p_2\} \ll 2^{11k/2}$. With $n = p_1 p_2$, we have that $2^k \mid \xi(n)$; therefore $\Omega(\xi(n)) \geq k \gg \log n$. Finally, let y be large and let $M = \prod_{p < y} p$. By the Prime Number Theorem, we have $\log M = (1 + o(1))y$. Let p_1 and p_2 be the first two primes in the arithmetic progression $1 \pmod{M}$. We again have that $\max\{p_1, p_2\} \ll M^{11/2}$, and with $n = p_1 p_2$ we have that $M \mid \xi(n)$. Thus,

$$\omega(\xi(n)) \gg \omega(M) = \pi(y) \gg \frac{\log M}{\log_2 M} \gg \frac{\log n}{\log_2 n},$$

which finishes the proof. \square

3. Average q -adic norm and order of $\varphi(n)$

Let q be a prime, and let $|m|_q$ be the q -adic norm of m , that is, $|m|_q = q^{-v_q(m)}$ where, as before, $v_q(m)$ is the largest power of q dividing m . In this section, we address the average value of $|\varphi(n)|_q$ and $v_q(\varphi(n))$.

Recall that an arithmetic function $f(n)$ is said to be *multiplicative* if $f(nm) = f(n)f(m)$ for any integers n and m with $\gcd(n, m) = 1$. Accordingly, if $f(nm) = f(n) + f(m)$ for any integers n and m with $\gcd(n, m) = 1$ then $f(n)$ is called *additive*.

In particular, $v_q(\varphi(n))$ is an additive function. Thus, $|\varphi(n)|_q$ is a bounded multiplicative function, and therefore it is natural that our principal tool is the following theorem of Wirsing [21].

Lemma 3. *Assume that a real-valued multiplicative function $f(n)$ satisfies the following conditions:*

- $f(n) \geq 0$, $n = 1, 2, \dots$;
- $f(p^v) \leq ab^v$, $v = 2, 3, \dots$, for some constants $a, b > 0$ with $b < 2$;
- there exists a constant $\tau > 0$ such that

$$\sum_{p \leq x} f(p) = (\tau + o(1)) \frac{x}{\log x}.$$

Then, for any $x \geq 0$,

$$\sum_{n \leq x} f(n) = \left(\frac{1}{e^{\gamma\tau} \Gamma(\tau)} + o(1) \right) \frac{x}{\log x} \prod_{p \leq x} \left(\sum_{v=0}^{\infty} \frac{f(p^v)}{p^v} \right),$$

where γ is the Euler constant, and

$$\Gamma(s) = \int_0^\infty e^{-t} t^{s-1} dt$$

is the Γ -function.

Lemma 4. For any fixed prime q ,

$$\prod_{p \leq x} \left(1 + \frac{|p-1|_q}{p-1} \right) = (\eta_q + o(1)) (\log_2 x)^{\alpha_q},$$

where $\alpha_q = (q^2 - q - 1)/(q^2 - 1)$, and η_q is a constant depending only on q .

Proof. We have

$$\log \left(1 + \frac{|p-1|_q}{p-1} \right) = \frac{|p-1|_q}{p} + O \left(\frac{|p-1|_q}{p^2} \right),$$

therefore the series

$$\zeta_q = \sum_p \left| \log \left(1 + \frac{|p-1|_q}{p-1} \right) - \frac{|p-1|_q}{p} \right|$$

converges absolutely. Hence, it is enough to show that

$$\sum_{p \leq x} \frac{|p-1|_q}{p} = \alpha_q \log_2 x + \beta_q + o(1) \quad (14)$$

holds with some constant β_q .

We have:

$$\begin{aligned} \sum_{p \leq x} \frac{|p-1|_q}{p} &= \sum_{k=0}^{\infty} \left(\sum_{\substack{p \leq x \\ p \equiv 1 \pmod{q^k}}} \frac{q^{-k}}{p} - \sum_{\substack{p \leq x \\ p \equiv 1 \pmod{q^{k+1}}}} \frac{q^{-k}}{p} \right) \\ &= S(x, 1) - (q-1) \sum_{k=1}^{\infty} q^{-k} S(x, q^k), \end{aligned} \quad (15)$$

where, as before, $S(x, q^k)$ is given by (2).

We write K for the largest positive integer such that $q^K \leq \log_2 x$; thus, $K \asymp \log_3 x$. Using the classical *Page bound* (see Chapter 20 of [6]) and partial summation (see a remark in Chapter 22 of [6]), we have

$$\pi(t; q^k, 1) = \frac{t}{(q-1)q^{k-1} \log t} + O \left(\frac{t}{q^k (\log t)^2} \right) \quad (16)$$

for all positive integers $k \leq K$ and real $t \geq e^K$.

Therefore, using the same partial summation arguments as in the proof of Theorem 1 of [18] (see also Lemma 6.3 of [17]), and using (16) in the appropriate place (starting with the value of $t \geq e^K$), we derive that for every $k \leq K$,

$$S(x, q^k) = \frac{\log_2 x}{(q-1)q^{k-1}} + A_{k,q} + O\left(\frac{1}{(\log x)^{1/2}}\right), \quad (17)$$

for some constants $A_{k,q}$ depending only on k and q . Moreover, by Theorem 1 of [18] or Lemma 6.3 of [17], $A_{k,q} = O(1)$ uniformly for q and $k = 0, 1, \dots$ (see (3)).

For $k \geq K$, we use the fact that

$$S(x, q^k) \ll \frac{\log_2 x}{(q-1)q^{k-1}} \quad (18)$$

(see the bound (3.1) in [7] and also Lemma 1 of [5]). Define

$$\beta_q = A_{k,0} - (q-1) \sum_{k \geq 1} \frac{A_{k,q}}{q^k}.$$

Using (17) and (18) in (15), and taking into account that

$$1 - (q-1) \sum_{k \geq 1} \frac{1}{(q-1)q^{2k-1}} = \frac{q^2 - q - 1}{q^2 - 1} = \alpha_q,$$

we get (14) and thus finish the proof. \square

Theorem 7. *For any prime q ,*

$$\sum_{n \leq x} |\varphi(n)|_q = (\gamma_q + o(1)) x (\log x)^{-q/(q^2-1)},$$

where γ_q is a constant depending only on q .

Proof. For $p \neq q$, we have

$$\sum_{v=0}^{\infty} \frac{|\varphi(p^v)|_q}{p^v} = 1 + \sum_{v=1}^{\infty} \frac{|p-1|_q}{p^v} = \frac{|p-1|_q}{p-1},$$

and certainly

$$\sum_{v=0}^{\infty} \frac{|\varphi(q^v)|_q}{q^v} = 1 + \sum_{v=1}^{\infty} \frac{1}{q^{2v-1}} = 1 + \frac{q}{q^2-1} = \frac{q^2+q-1}{q^2-1}.$$

Combining Lemma 3 and Lemma 4, we obtain the desired result. \square

We now show that the classical *Turán–Kubilius* inequality can be used to study the normal order of $v_q(\varphi(n))$.

Theorem 8. *For any prime q , the estimate*

$$v_q(\varphi(n)) = \left(\frac{q}{(q-1)^2} + o(1) \right) \log_2 n$$

holds for almost all positive integers n .

Proof. Because $v_q(\varphi(n))$ is an additive function, by the Turán–Kubilius inequality (see [14], [19]), we have

$$\frac{1}{x} \sum_{n \leq x} |v_q(\varphi(n)) - A_q(x)|^2 \ll D_q(x)$$

where

$$A_q(x) = \sum_{p^r \leq x} \frac{v_q(\varphi(p^r))}{p^r} \quad \text{and} \quad D_q(x) = \sum_{p^r \leq x} \frac{v_q^2(\varphi(p^r))}{p^r},$$

and in both sums the summation is extended over all prime powers $p^r \leq x$. Thus, it is enough to show that

$$A_q(x) = \left(\frac{q}{(q-1)^2} + o(1) \right) \log_2 x \quad \text{and} \quad D_q(x) = o((\log_2 x)^2). \quad (19)$$

Because $v_q(\varphi(p)) \ll \log p$, using the Prime Number Theorem, we derive that

$$\sum_{\substack{p^r \leq x \\ r \geq 2}} \frac{v_q(\varphi(p))}{p^r} \ll \sum_{r=2}^x \sum_{k=2}^{\infty} \frac{\log k}{(0.5k \log k)^r} \ll \sum_{r=2}^x \sum_{k=2}^{\infty} \frac{1}{k^r} \ll \sum_{r=2}^x 2^{-r} \ll 1.$$

Thus

$$A_q(x) = \sum_{p \leq x} \frac{v_q(\varphi(p))}{p} + O(1) = \sum_{\substack{p \leq x \\ p \neq q}} \frac{v_q(\varphi(p))}{p} + O(1).$$

Furthermore, as in the proof of Lemma 4, we derive that

$$\begin{aligned} \sum_{\substack{p \leq x \\ p \neq q}} \frac{v_q(\varphi(p))}{p} &= \sum_{k=1}^{\infty} \left(\sum_{\substack{p \leq x \\ p \equiv 1 \pmod{q^k}}} \frac{k}{p} - \sum_{\substack{p \leq x \\ p \equiv 1 \pmod{q^{k+1}}}} \frac{k}{p} \right) \\ &= \sum_{k=1}^{\infty} S(x, q^k) = \left(\frac{q}{(q-1)^2} + o(1) \right) \log_2 x. \end{aligned}$$

Similar arguments show that $D_q(x) = O(\log_2 x)$ (in fact, our arguments give an asymptotic formula for $D_q(x)$). Therefore, we obtain (19), which finishes the proof. \square

4. Distribution of $\Omega(\varphi(n)) - \omega(\varphi(n))$

It has been shown in [8] that for almost all positive integers n , both $\Omega(\varphi(n))$ and $\omega(\varphi(n))$ are close to $0.5(\log_2 n)^2$. Here, we study the behavior of the difference $\Omega(\varphi(n)) - \omega(\varphi(n))$.

Theorem 9. *The estimate*

$$\Omega(\varphi(n)) - \omega(\varphi(n)) = (1 + o(1)) \log_2 n \log_4 n$$

holds for almost all positive integers n .

Proof. By Theorem 5, we know that

$$\Omega(\xi(n)) = (1 + o(1)) \log_2 n \log_4 n$$

holds for almost all positive integers n . Since

$$\Omega(\varphi(n)) - \omega(\varphi(n)) = \Omega(\varphi(n)) - \omega(\lambda(n)) \geq \Omega(\varphi(n)) - \Omega(\lambda(n)) \geq \Omega(\xi(n)),$$

we see that

$$\Omega(\varphi(n)) - \omega(\varphi(n)) \geq (1 + o(1)) \log_2 n \log_4 n$$

holds for almost all positive integers n .

To obtain the upper bound, let x be a large positive real number, and let $y = (\log_2 x)^2$. The argument on page 404 of [16] shows that the set of all positive integers $n \leq x$ such that $\varphi(n)$ is not divisible by the square of any prime $q > y$ has cardinality $x + o(x)$ (see the bound on $\#\mathcal{E}_2$ in Theorem 9 of [16]). Thus, for all but $o(x)$ positive integers $n \leq x$, we have that

$$\Omega(\varphi(n)) - \omega(\varphi(n)) = \Omega_y(\varphi(n)) - \omega_y(\varphi(n)) \leq \Omega_y(\varphi(n)).$$

Now using (9) (which is established with the same value of y), we finish the proof. \square
