vectors and they therefore belong to the centre of  $D$  since the eigenvectors span  $D$ . Each eigenvalue is a root of  $f(X)$  so the degree of  $g(X)$  is no larger than that of  $f(X)$ . But  $g(\theta) = 0$  so we must have  $g(X) = f(X)$ . Since each  $\theta_i$  must be a root of the minimal polynomial of  $T_\theta$  this proves

(2.4) *The minimal polynomial of  $T_\theta$  is  $f(X)$ .*

As immediate consequences we have

$$(2.5) \quad \dim_F D = \dim_K F = \text{degree of } f = m.$$

$$(2.6) \quad \dim_K D = m^2.$$

Finally, we prove

(2.7) *If  $E = K(\theta')$  and  $f(\theta') = 0$ , then for some non-zero element  $d$  of  $D$ ,  $d E d^{-1} \subseteq F$ .*

To see this, consider the linear transformation  $T_{\theta'}$ . Since  $f(T_{\theta'}) = 0$  there is an eigenvalue  $\lambda \in F$  of  $T_{\theta'}$  and a corresponding eigenvector  $d$  such that  $d \theta' = \lambda d$ ; it follows that  $d E d^{-1} \subseteq F$ .

*Remark.* The assumption on the field  $F$  amounts to supposing that  $F/K$  is a finite Galois extension and the proof of (2.4) shows that  $N(F)^\#/F^\#$  is isomorphic to its Galois group. (Where  $F^\#$  denotes the set of non-zero elements of  $F$ .)

### 3. WEDDERBURN'S THEOREM

This proof follows van der Waerden [14, p. 203]. The counting argument was used by Artin [1] in his proof of the same theorem.

**THEOREM.** *Every finite division ring is a field.*

*Proof.* Suppose that  $D$  is a finite division ring with centre  $K$  and maximal subfield  $F$ . If the order of  $F$  is  $q$ , then the elements of  $F$  constitute all the roots of the polynomial  $X^q - X$ ; hence any two finite fields of the same order are isomorphic. The multiplicative group of a finite field is cyclic, so  $F = K(\theta)$  for some  $\theta$ . Any element of  $D$  is contained in a maximal subfield, which by (2.5) has the same order as  $F$  and hence by (2.7) any element of the multiplicative group  $G$  of non-zero elements of  $D$  belongs to a conjugate of  $H$ , the multiplicative group of non-zero elements of  $F$ . The

number of conjugates of a subgroup is the index of its normalizer, so  $H$  has at most  $|G : H|$  conjugates in  $G$  and hence the union of the conjugates contains at most  $|G : H|(|H| - 1) + 1 = |G| - |G : H| + 1$  elements. This number is less than  $|G|$  except when  $G = H$ . Hence  $D = F$  is a field.

#### 4. FROBENIUS' THEOREM

Let  $\mathbf{R}$  denote the field of real numbers,  $\mathbf{C}$  the field of complex numbers and  $\mathbf{H}$  the division ring of quaternions. The following proof makes use of the fundamental theorem that every polynomial with coefficients in  $\mathbf{C}$  has a root in  $\mathbf{C}$ .

**THEOREM.** *Let  $D$  be a division ring which contains the real numbers  $\mathbf{R}$  in its centre and suppose that every element of  $D$  satisfies a polynomial with coefficients in  $\mathbf{R}$ . Then  $D$  is isomorphic to one of  $\mathbf{R}$ ,  $\mathbf{C}$  or  $\mathbf{H}$ .*

*Proof.* Suppose that  $D$  is not isomorphic to  $\mathbf{R}$  or  $\mathbf{C}$ . It follows that the maximal subfield  $F$  of  $D$  is isomorphic to  $\mathbf{C}$ , the centre  $K$  of  $D$  is isomorphic to  $\mathbf{R}$  and  $F = K(i)$  where  $i^2 = -1$ . Let  $j$  be an eigenvector of  $T_i$  corresponding to the eigenvalue  $-i$ . Then  $ji = -ij$  and  $j^2$  commutes with  $j$  and  $F$ . From (2.2) and (2.3) the elements 1 and  $j$  form an  $F$ -basis for  $D$  and therefore  $j^2 = \alpha$  belongs to  $K$ . If  $\alpha = \beta^2$  for some  $\beta \in K$  then  $(j-\beta)(j+\beta) = 0$  and  $j$  belongs to  $K$ , which is not the case; hence  $\alpha = -\beta^2$  for some  $\beta \in K$ . Replacing  $j$  by  $j\beta^{-1}$  we obtain a  $K$ -basis 1,  $i$ ,  $j$ ,  $ij$  for  $D$  such that  $i^2 = j^2 = -1$  and  $ij = -ji$ . That is,  $D$  is isomorphic to  $\mathbf{H}$ .

An almost identical argument shows that if the dimension of  $D$  over its centre  $K$  is 4 and the characteristic is not 2, then  $D$  has a  $K$ -basis 1,  $i$ ,  $j$ ,  $ij$  where  $i^2 = \alpha$ ,  $j^2 = \beta$  and  $ij = -ji$  for some  $\alpha, \beta \in K$ .

#### 5. OTHER PROOFS OF WEDDERBURN'S THEOREM

The original proofs of the theorem of §3 were given first by Wedderburn [15] in 1905 and then by Dickson [5] in the same year; they depend on certain divisibility properties of the integers. The neatest proof along these lines is that of Witt [16]. Elementary proofs which avoid the use of such number theory have been given by Artin [1] and Herstein [7]. And
