$>\sigma_{1}-\varepsilon$. If $w$ is defined by $w(z)=z+e^{i \theta} / z$ and $f=w \circ h^{-1}$, then $f$ is univalent in $A$ and

$$
\left\|S_{f}\right\|_{A}=\left\|S_{w}-S_{h}\right\|_{D} \geqslant\left|S_{w}(0)-S_{h}(0)\right|=\left|6 e^{i \theta}+S_{h}(0)\right| .
$$

By choosing $\varphi$ suitably we obtain $\left\|S_{f}\right\|_{A}>6+\sigma_{1}-\varepsilon$.

## 5. Schwarzian derivative and univalence

5.1 Constant $\sigma_{3}$. Let $A$ again be a simply connected domain with more than one boundary point. As a kind of opposite to the constant $\sigma_{2}$ we define

$$
\sigma_{3}=\sup \left\{a \mid\left\|S_{f}\right\| \leqslant a \text { implies } f \text { univalent in } A\right\}
$$

Note that the number $a=0$ is always in the above set. In this definition, sup can be replaced by max, as can be shown by a standard normal family argument.

Nehari [12] proved that in a disc, the condition $\left\|S_{f}\right\| \leqslant 2$ implies the univalence of $f$, and Hille [5] showed that the bound 2 is best possible. In other words, $\sigma_{3}=2$ for a disc.

A closer study of $\sigma_{3}$ leads to the universal Teichmüller space and reveals an intrinsic significance of quasiconformal mappings in the theory of univalent functions. The gist is the following result.

Theorem 5.1. The constant $\sigma_{3}$ is positive if and only if $A$ is bounded by a quasicircle.

Proof: The sufficiency of the condition was established by Ahlfors [1] who actually proved more: If $A$ is bounded by a $K$-quasicircle, there is an $\varepsilon>0$ depending only on $K$, such that whenever $\left\|S_{f}\right\|_{A}<\varepsilon$, then $f$ is univalent and can be continued to a quasiconformal mapping of the plane. In the proof, the extension of the given meromorphic $f$ is explicitly constructed by means of a continuously differentiable quasiconformal reflection $\varphi$ in $\partial A$ with bounded $|d \varphi| /|d z|$ (cf. 3.3).

The necessity was proved by Gehring [2]. His proof was in two steps. It was first shown, by aid of an example, that if $A$ is not $b$-locally connected for any $b$, then $\sigma_{3}=0$. After this, the desired conclusion was drawn from the result we stated above as Lemma 3.2.
5.2 Universal Teichmüller space. Henceforth, we assume that the domain $A$ is bounded by a quasicircle. Let $Q(A)$ be the Banach space
consisting of all holomorphic functions $\varphi$ of $A$ with finite norm. We introduce the subsets
$U(A)=\left\{\varphi=S_{f} \mid f\right.$ univalent in $\left.A\right\}$,
$T(A)=\left\{S_{f} \in U(A) \mid f\right.$ can be extended to a quasiconformal mapping of the plane $\}$.
Both sets are well defined. The set $T(A)$ is called the universal Teichmüller space of $A$.

Theorem 5.2. The sets $T(A)$ and $U(A)$ are connected by the relation $T(A)=$ interior of $U(A)$.

Proof: We first show that $T(A)$ is open. Choose $S_{f} \in T(A), S_{h} \in Q(A)$, and set $g=h \circ f^{-1}$. Then $g$ is meromorphic in the domain $f(A)$. Since $\partial A$ is a quasicircle, $\partial f(A)$ is also a quasicircle. By the theorem of Ahlfors cited in the proof of Theorem 5.1, there is an $\varepsilon>0$ such that if

$$
\begin{equation*}
\left\|S_{g}\right\|_{f(A)}<\varepsilon \tag{5.1}
\end{equation*}
$$

then $S_{g} \in T(f(A))$. Now, choose $h$ so that $\left\|S_{f}-S_{h}\right\|_{A}<\varepsilon$. Then (5.1) holds, and it follows that $S_{h}=S_{g \circ f} \in T(A)$.

After this it suffices to prove that int $U(A) \subset T(A)$. Choose $S_{f} \in \operatorname{int} U(A)$ and then an $\varepsilon>0$, so that the ball $B=\{\varphi \in Q(A) \| \varphi$ $\left.-S_{f} \|<\varepsilon\right\}$ is contained in $U(A)$. Let $g$ be an arbitrary meromorphic function in $f(A)$ for which $\left\|S_{g}\right\|_{f(A)}<\varepsilon$. If $h=g \circ f$, then $\left\|S_{f}-S_{h}\right\|_{A}$ $=\left\|S_{g}\right\|_{f(A)}<\varepsilon$. Thus $S_{h} \in U(A)$. But then also $g=h \circ f^{-1}$ is univalent, and we have proved that $\sigma_{3}$ is positive for the domain $f(A)$. By Theorem 5.1, the boundary $\partial f(A)$ is a quasicircle. Hence, by the remark in 3.3, $S_{f} \in T(A)$.

Corollary 5.1. If $f$ is univalent in $A$ and $\left\|S_{f}\right\|_{A}<\sigma_{3}$, then $f$ can be extended to a quasiconformal mapping of the plane.

Proof: This follows immediately from Theorem 5.2, in view of our previous remark that the closed ball $\left\{\varphi \in Q(A) \mid\|\varphi\|_{A} \leqslant \sigma_{3}\right\}$ is contained in $U(A)$.

By this Corollary, we have for $A$,
$\sigma_{3}=\sup \{a \mid$

extended to a quasiconformal mapping of the plane $\}.$
5.3 New characterization for $\sigma_{3}$. Theorem 5.2 was proved by Gehring [2] in the case where $A$ is a half-plane. As is seen from the above proof, the generalization for an arbitrary $A$ is immediate. In fact, the sets $Q(A)$, $U(A)$ and $T(A)$ corresponding to different domains $A$ are isomorphic:

Lemma 5.1. Let $h$ be a conformal mapping of the upper half-plane $H$ onto $A$. Then the mapping $h^{*}: Q(A) \rightarrow Q(H)$, defined by $h^{*}\left(S_{f}\right)=S_{f \circ h}$, is a bijective isometry. It maps $U(A)$ and $T(A)$ onto $U(H)$ and $T(H)$, respectively.

Proof: Clearly $h^{*}$ is well defined and a bijection of $Q(A), U(A)$ and $T(A)$ onto $Q(H), U(H)$ and $T(H)$, respectively. That $h^{*}$ is an isometry follows from formula (4.3).

The function $h^{*}$ maps the origin of $Q(A)$ onto the point $S_{h} \in T(H)$, which has the distance $\sigma_{1}$ from the origin of $Q(H)$. If $B=\{\varphi \in Q(A) \mid$ $\left.\|\varphi\|_{A} \leqslant \sigma_{3}\right\}$, then

$$
h^{*}(B)=\left\{\psi \in Q(H) \mid\left\|\psi-S_{h}\right\| \leqslant \sigma_{3}\right\} .
$$

From this and the definition of $\sigma_{3}$ we infer that $\sigma_{3}$ is equal to the distance from the point $S_{h}$ to the boundary of $U(H)$. The following characterization seems to be more useful:

Lemma 5.2. The constant $\sigma_{3}$ of $A$ is equal to the distance of the point $S_{h}$ to the boundary of $T^{\prime}(H)$.

Proof: Let $d$ denote the distance function in $Q$. Since $T(H) \subset U(H)$ we conclude from what we just said above that $\sigma_{3} \geqslant d\left(\left\{\mathrm{~S}_{h}\right\}, U(H)\right.$ $-T(H)$ ). On the other hand, it follows from Theorem 5.2 that int $B \subset T(A)$ and hence int $h^{*}(B) \subset T(H)$. Therefore, $\sigma_{3} \leqslant d\left(\left\{S_{h}\right\}, U(H)-T(H)\right)$.

A standard normal family argument shows that $U(A)$ is a closed subset of $Q(A)$. Therefore, the closure of $T(A)$ is contained in $U(A)$. Gehring [3] showed recently that this inclusion is proper, thus disproving a famous conjecture of Bers.

However, it is true that on every sphere $\|\varphi\|=r$ of $Q(H), 2 \leqslant r \leqslant 6$, there are points of $U(H)-T(H)$ which belong to the closure of $T(H)$ ([9]).
5.4 Estimates for $\sigma_{3}$. Lemma 5.2 can be used to deriving estimates for $\sigma_{3}$ in terms of $\sigma_{1}$ ([9]). Suppose first that $0 \leqslant \sigma_{1}<2$. Then $S_{h}$ lies in the ball $\{\varphi \in Q(H) \mid\|\varphi\|<2\}$ which is a subset of $T(H)$. Since $\left\|S_{h}\right\|=\sigma_{1}$,
we conclude that $d\left(\left\{S_{h}\right\}, U(H)-T(H)\right) \geqslant 2-\sigma_{1}$. Consequently, by Lemma 5.2,

$$
\begin{equation*}
\sigma_{3} \geqslant 2-\sigma_{1} \tag{5.2}
\end{equation*}
$$

In order to prove that this inequality is sharp, we consider the point $S_{w}$, where $w$ is the restriction to $H$ of a branch of the logarithm. Since the boundary of $w(H)$ is not a quasicircle, $S_{w} \in U(H)-T(H)$. From $S_{w}(z)$ $=z^{-2} / 2$ it follows that $\left\|S_{w}\right\|_{H}=2$. Let $h$ be determined by the condition $S_{h}=r S_{w}, 0<r<1$, and set $A=h(H)$. From $\left\|S_{h}\right\|_{H}<2$ it follows that $S_{h} \in T(H)$, and so $\partial A$ is a quasicircle. Now

$$
\sigma_{3}=d\left(\left\{S_{h}\right\}, U(H)-T(H)\right)=\left\|S_{w}-S_{h}\right\|=2(1-r)=2-\sigma_{1},
$$

showing that (5.2) is sharp.
Suppose that $2 \leqslant \sigma_{1}<6$. We then conclude from the remark at the end of 5.3 that, even though $\sigma_{3}>0$ for each $A$, we have $\inf \sigma_{3}=0$ for every $\sigma_{1}$.

Similarly, Lemma 5.2 can be used to deriving the upper estimate

$$
\sigma_{3} \leqslant \min \left(2,6-\sigma_{1}\right)
$$

(For the details we refer to [9].)
