GEOMETRY AND COMBINATORICS OF GROUPS GENERATED BY REFLECTIONS

by Eugene GUTKIN ¹⁾

§ 0. INTRODUCTION

Let M be a connected topological manifold. A continuous transformation s of M is called a reflection if $s^2 = 1$ and the set M_s of fixed points of s has codimension one. A reflection s is called separating if $M \setminus M_s$ is disconnected.

In this paper we consider groups $G: M \rightarrow M$ of transformations generated by separating reflections and acting properly discontinuously on M . We call them reflection groups for brevity. Reflection groups occur in various branches of mathematics. Weyl groups of semisimple Lie groups is a well known example (see [2] and the references there). Another important example of reflection groups is the Weyl groups of Kac-Moody Lie groups (cf. [13]) and of the loop groups (cf. [16]) acting properly discontinuously on the Tits cone (cf. [20]).

Reflection groups have applications in such different areas as the classification of singularities (cf. [1], [14], [17] to mention but a few), integrable quantum many body problems (cf. [5]-[7], [10] and [12]) and the minimal surfaces ([15]). Recently M. Davis [3] found interesting applications of reflection groups in topology.

In the majority of applications of reflection groups they act by linear, affine, projective or hyperbolic transformations on linear, affine, projective or hyperbolic spaces respectively. But the most useful properties of reflection groups are independent of the particular nature of the group action. The properties I have in mind are combinatorial or geometric (cf. Theorem 1 and

¹⁾ Research partially supported by NSF Grant DMS 84-03238.

Corollary 5 in § 1) which hold for reflection groups in general as was demonstrated by Davis [3] (see also [18]).

The proofs of these general properties in the literature depend on the particular type of the reflection groups considered. The best known proofs are those in [2] for the linear (or affine) reflection groups acting properly discontinuously on the whole space, and Davis [3] adapted them to the general case of topological reflection groups.

The purpose of this paper is to supply geometric proofs of the basic properties of general reflection groups as opposed to adapting the formal arguments of [2]. For simplicity of exposition we assume in the paper that M is a differentiable (actually C^1) manifold and that the group action is C^1 . Extension to the topological manifolds does not require new ideas and is left to the reader.

The rationale for this paper is twofold. First, the basic properties of reflection groups are stated (and proved) here in a form particularly useful for applications (cf. [5], [9], [11]). Second and more important, the simplicity of the geometric proofs presented here will make the subject more accessible to the general mathematical public.

In conclusion let me mention that reflection groups that do not act properly discontinuously are also useful (cf. [19], [4], [8]) but the results of the paper do not extend to them.

I would like to thank Mike Davis and the referee for pointing out an error in the original version of the paper. ¹⁾

§ 1. GEOMETRY AND COMBINATORICS

Throughout the paper M is a connected differentiable manifold (possibly with boundary).

Definition 1. A reflection of M is a diffeomorphism s such that $s^2 = 1$ and the set M_s of fixed points of s has codimension 1. A reflection s is called separating if $M \setminus M_s$ is disconnected. A reflection group W acting on M is a discrete group of diffeomorphisms of M generated by separating reflections.

¹⁾ I. N. Bernstein told me that E. B. Vinberg has an unpublished manuscript on reflection groups which is similar to this one.

LEMMA 1. Let s be a reflection of M . Then $M \setminus M_s$ has at most two connected components.

Proof. Let $x_0, x_1 \in M \setminus M_s$ and let $x(t)$ be a continuous path joining them. We can assume without loss of generality that $x(t)$ is piecewise differentiable and that it intersects M_s transversally. Let $x(t_1), \dots, x(t_N)$ be the points of intersection. Consider the new path $\tilde{x}(t)$ where

$$\tilde{x}(t) = x(t), \quad 0 \leq t \leq t_1, \quad \tilde{x}(t) = sx(t), \quad t_1 \leq t \leq t_2,$$

$$\tilde{x}(t) = x(t), \quad t_2 \leq t \leq t_3, \text{ etc.}$$

(see fig. 1). Deform the path $\tilde{x}(t)$ slightly in small neighborhoods of $x(t_1), \dots, x(t_N)$ to make it come off M_s (if $\tilde{x}(t)$ does not cross M_s at t_i).

FIGURE 1

$M \setminus M_s$ has at most two connected components

The resulting path $x'(t)$ does not intersect M_s at all if N is even and intersects M_s only at $x(t_N)$ if N is odd. Thus any $x, y \in M \setminus M_s$ can be joined by a continuous path intersecting M_s at most once.

Assume that $M \setminus M_s$ has three connected components X, Y, Z and choose points x, y, z in X, Y, Z respectively. Then there are paths $\gamma, \tilde{\gamma}$ from x to y

and from y to z respectively intersecting M_s once. The path $\tilde{\gamma}\gamma$ goes from x to z and intersects M_s twice. By previous argument we can find another path γ' from x to z that does not intersect M_s at all. This contradiction proves the Lemma.

COROLLARY 0. *Let $M \setminus M_s$ be disconnected and let $x, y \in M \setminus M_s$. Let γ be a continuous path in M joining x with y and intersecting M_s transversally. Then x, y belong to the same component of $M \setminus M_s$ if and only if γ intersects M_s an even number of times.*

Proof. Let γ intersect M_s N times. By the argument of Lemma 1, we can find another path γ' from x to y that intersects M_s once if N is odd and does not intersect M_s if N is even. Thus it suffices to prove that if γ joining x with y intersects M_s once then x and y belong to different connected components of $M \setminus M_s$. Assume the opposite and let z belong to the other component. Then there is a path $\tilde{\gamma}$ from y to z intersecting M_s once. The composition $\tilde{\gamma}\gamma$ joins points in different connected components of $M \setminus M_s$ and intersects M_s twice. By the argument of Lemma 1, this is impossible.

Denote by M/s the quotient of M by the action of s endowed with the natural topology.

PROPOSITION 1. *Let s be a reflection of M .*

- (i) *Assume that s is separating. Then M is orientable if and only if M/s is.*
- (ii) *Assume that s is not separating. If M is orientable then M/s is not orientable.*

Proof. Let X be a connected manifold with the boundary $\partial X \neq \emptyset$. Define the doubling dX of X as the manifold obtained by gluing two copies of X along the common boundary. Clearly dX is orientable if and only if X is.

Let M_s separate M and let X_0, Y_0 be the connected components of $M \setminus M_s$. Let $X = X_0 \cup M_s, Y = Y_0 \cup M_s$ be their closures in M . Then $s: X \rightarrow Y$ is a diffeomorphism which identifies X, Y with M/s and M with dX . This proves (i).

(ii) Let $x \in M$ be sufficiently close to M_s . Then x and sx belong to the same open ball in M and we orient the tangent spaces at x and sx simultaneously. Let γ be a continuous path in $M \setminus M_s$ from x to sx . Since M

is orientable, moving along γ does not change the orientation. Since s reverses the orientation, moving along the loop $p\gamma$ in the quotient $p: M \rightarrow M/s$ we come back to px with the orientation reversed.

Examples. 1. Let $M = S^1 \times S^1$ be the twodimensional torus and let s be the reflection about the diagonal (see fig. 2, a)). Then M/s is the Moebius band.

a) $M = S^1 \times S^1$

$M/s = \text{Moebius band}$

b) $M = \text{Moebius band}$

$M/s = \text{cylinder}$

FIGURE 2

2. Let s be the reflection of the Moebius band M about the midline (see fig. 2, b)). Then M/s is the cylinder.

Remark. Proposition 1, (ii) shows that if s is not separating then M and M/s can not be both orientable. The following example shows that M and M/s can be both nonorientable.

3. Let M be the product of two Moebius bands and let s be the product of the reflection in midline (Example 2) and the identity map. Then M/s is the product of the cylinder and the Moebius band. Thus s does not separate M and both M and M/s are not orientable.

COROLLARY 1. *If M is simply connected then any reflection s of M is separating.*

Proof. Since s has fixed points, M/s is simply connected, thus orientable. If s is not separating then, by Proposition 1, (ii), M is not orientable, contrary to the assumption.

In the rest of the paper we consider only separating reflections and groups generated by them. By Corollary 1, if M is simply connected (which holds in many applications) then the assumption is automatically satisfied.

Let us establish some terminology. The closures M_s^ε , $\varepsilon = \pm 1$, of connected components of $M \setminus M_s$ are the two halfspaces corresponding to s . If $A \subset M$ intersects only one connected component of $M \setminus M_s$ we denote the corresponding halfspace by $M_s(A)^+$ and the other one by $M_s(A)^-$.

Let W be a reflection group acting on M and let $R \subset W$ be the set of reflections in W . The sets M_s , $s \in R$ are called the (reflecting) walls of M and the closures of connected components of $M_{\text{reg}} = M \setminus \bigcup_{s \in R} M_s$ are the chambers of M . M_{reg} is the set of regular points of M . Since a wall M_s defines s uniquely, we identify R with the set of walls of M . Points $x \in M$ that belong to no more than one wall are the semiregular points of M . The walls of a chamber C are such M_s that $\dim(M_s \cap C) = n-1$, their intersections with C are the faces of C . Walls of C correspond to a subset $S_C \subset R$. Nonempty intersections of faces of C are the facets of C .

Two chambers $C \neq D$ are adjacent if they have a common face. Let M_r be the unique wall containing this face, then $D = rC$. A sequence C_0, C_1, \dots, C_N of chambers is a gallery (of length N , going from C_0 to C_N) if for $i = 1, \dots, N$ the chambers C_{i-1} and C_i are adjacent. The sequence (r_1, \dots, r_N) of reflections defined by $C_i = r_i C_{i-1}$ is called the reflection sequence corresponding to the gallery C_0, \dots, C_N . A gallery C_0, \dots, C_N crosses M_r if r is contained in the corresponding sequence (r_1, \dots, r_N) . A minimal gallery going from C to D is a gallery of minimal length which is by definition the distance $d(C, D)$ between C and D . A wall M_r separates chambers C and D if $C \subset M_r^\varepsilon$ and $D \subset M_r^{-\varepsilon}$. Denote by $R(C, D) \subset R$ the set of walls separating C from D . The group W acts on R by conjugations $r \rightarrow grg^{-1}$ which we denote for brevity by $g \cdot r$. Then $gM_r^\varepsilon = M_{g \cdot r}^\delta$, $\varepsilon, \delta = \pm 1$.

PROPOSITION 2. Let $C = C_0, C_1, \dots, C_N = D$ be a gallery and let (r_1, \dots, r_N) be the corresponding sequence of reflections.

- (i) The set of reflections r contained in (r_1, \dots, r_N) an odd number of times is $R(C, D)$.
- (ii) The following assertions are equivalent:
 - a) gallery C_0, \dots, C_N is minimal;
 - b) $d(C_i, C_j) = |i - j|$ for any $i, j = 0, \dots, N$;
 - c) there are no repetitions in the sequence (r_1, \dots, r_N) .

Proof. A differentiable path $\{x(t): 0 \leq t \leq 1\}$ on M is called regular if for all but a finite number $0 < t_1 < \dots < t_N < 1$ of moments of time $x(t)$ is regular, $x(t_i)$ is semiregular for $i = 1, \dots, N$ and the curve $x(t)$ is transversal to the set $\bigcup_{s \in R} M_s$. Then for $t \neq t_1, \dots, t_N$ $x(t)$ belongs to a unique chamber and the sequence C_0, \dots, C_N thus defined is a gallery with t_i

FIGURE 3

To the proof of Proposition 2. Galleries and paths along them

being the moment of time when $x(t)$ crosses from C_{i-1} to C_i . We say that C_0, \dots, C_N is the gallery along the path $\{x(t)\}$. Given a gallery C_0, \dots, C_N there is always a regular path $\{x(t)\}$ such that C_0, \dots, C_N is the gallery along it. We say that $\{x(t)\}$ goes along the gallery.

Let C_0, \dots, C_N be a gallery going from $C = C_0$ to $D = C_N$ and let $\{x(t)\}$ be a regular path along it. For any $r \in R$ let $t_{i_1} < \dots < t_{i_{N(r)}}$ be the consecutive moments of time when $\{x(t)\}$ intersects M_r . By Corollary 0, $N(r)$ is even (resp. odd) if and only if $r \notin R(C, D)$ (resp. $r \in R(C, D)$) which proves (i). Assertions a) and b) of (ii) are obviously equivalent. By (i) every $r \in R(C, D)$ is contained in (r_1, \dots, r_N) at least once, thus $N \geq |R(C, D)|$. Assume that $N > |R(C, D)|$. Then either there is $r \notin R(C, D)$ that occurs in (r_1, \dots, r_N) (necessarily an even number of times) or there is $r \in R(C, D)$ that occurs in (r_1, \dots, r_N) more than once. Assume the first possibility and let r occur $2m$ times in (r_1, \dots, r_N) . Using the proof of Lemma 1 we construct a new regular path $\{x'(t)\}$ which joins $x(0)$ with $x(1)$ and does not cross M_r at all (see fig. 3, a)). The gallery along $\{x'(t)\}$ has $N + 1 - 2m$ chambers and does not cross M_r . Analogous argument shows that if there is $r \in R(C, D)$ that occurs $2m + 1 > 1$ times in (r_1, \dots, r_N) then there is a new gallery from C to D which is by $2m$ shorter than C_0, \dots, C_N and crosses M_r once (see fig. 3, b)). Thus the sequence (r_1, \dots, r_N) corresponding to a minimal gallery can contain only $r \in R(C, D)$ and no more than once. On the other hand by (i), it must contain every $r \in R(C, D)$ at least once. This proves the Proposition and the following.

COROLLARY 2. 1) A gallery $C = C_0, \dots, C_N = D$ is minimal if and only if $N = |R(C, D)|$. Thus $d(C, D) = |R(C, D)|$. 2) For any gallery $C = C_0, \dots, C_N = D$, $(-)^N = (-)^{d(C, D)}$.

COROLLARY 3. Let $D \neq C$ be two chambers, let M_s (resp. M_r) be a wall of C (resp. D) such that $r, s \in R(C, D)$. Then there exists a minimal gallery $C_0 = C, \dots, C_N = D$ such that $C_1 = sC$ and $C_{N-1} = rD$.

Proof. If $d(C, D) = 1$ then $r = s$ and the assertion is trivial. If $t \in R$ and $t \neq s$ then t cannot separate sC from C . If besides $t \in R(C, D)$ then $C, sC \subset M_t(D)^-$ and if $t \notin R(C, D)$ then $C, sC \subset M_t(D)^+$. Therefore $R(sC, D) = R(C, D) \setminus \{s\}$ and $d(sC, D) = d(C, D) - 1$. This proves the assertion by induction on $d(C, D)$.

The group W naturally acts on the set of chambers of M . Choose one chamber C_+ to be the fundamental chamber and let $S = S_{C_+}$ be the set of reflections in the walls of C_+ . Elements $s \in S$ are called simple reflections.

PROPOSITION 3.

- (i) W acts simply transitively on the set of chambers.
- (ii) S generates W .
- (iii) Any $r \in R$ is conjugate to some $s \in S$.
- (iv) Let $g \in W$ and let $g = s_1 \dots s_N$ be a decomposition of g into simple reflections. Then the sequence

$$C_0 = C_+, C_1 = s_1 C_+, \dots, C_i = s_1 \dots s_i C_+, \dots, C_N = s_1 \dots s_N C_+$$

is a gallery. This establishes a one to one correspondence between the words in s_i and galleries starting from C_+ .

Proof. Denote $d(C_+, C)$ by $d(C)$ and $R(C_+, C)$ by $R(C)$. Let \tilde{W} be the subgroup of W generated by S . We have seen in the proof of Corollary 3 that if $d(C) > 0$ then there is $r \in R(C)$ such that $d(rC) = d(C) - 1$. Assuming that $rC = wC_+$ for some $w \in \tilde{W}$ we have $r = wsw^{-1}$ for some $s \in S$, thus $r \in \tilde{W}$ and $C = r \cdot rC = rwC_+$ where $rw \in \tilde{W}$. This proves by induction on $d(C)$ that \tilde{W} acts transitively on the set of chambers.

Let $r \in R$ and let C be such that M_r is a wall of C . Then there is $w \in \tilde{W}$ such that $w^{-1}C = C_+$ thus $w^{-1}M_r$ is a wall of C_+ , that is $w^{-1}M_r = M_s$ for some $s \in S$, therefore $r = wsw^{-1}$ which shows that $R \subset \tilde{W}$ and proves (iii). The group W is generated by R and $R \subset \tilde{W}$ thus $W = \tilde{W}$ which proves (ii). Let $C_i, i = 0, \dots, N$ be the sequence of chambers defined in (iv). Since

$$C_{i+1} = (s_1 \dots s_i)s_{i+1}(s_i \dots s_1)s_1 \dots s_i C_+ = r_{i+1}C_i$$

and since $r_{i+1} = (s_1 \dots s_i)s_{i+1}(s_1 \dots s_i)^{-1} \in S_{C_i}$ the chambers C_{i+1} and C_i are adjacent, thus C_0, \dots, C_N is a gallery going from C_+ to gC_+ . Let $C_0 = C_+, \dots, C_N$ be any gallery and let (r_1, \dots, r_N) be the corresponding sequence of reflections. Set $g_i = r_i \dots r_1, i = 1, \dots, N$. Then $C_i = g_i C_+$ and $g_i^{-1}r_{i+1}g_i \in S$ for $i = 1, \dots, N$. Denote $g_i^{-1}r_{i+1}g_i$ by s_{i+1} . Then $g_{i+1} = r_{i+1}g_i = g_i s_{i+1}$ which shows by induction that $g_i = s_1 \dots s_i$ for $i = 1, \dots, N$. Thus the gallery C_0, \dots, C_N corresponds to the word $s_1 \dots s_{i+1}$ which proves (iv). In particular, two words $s_1 \dots s_N$ and $s'_1 \dots s'_M$ represent the same $g \in W$ if and only if the corresponding galleries $C_+ = C_0, \dots, C_N$ and $C_+ =$

$= C'_0, \dots, C'_M$ lead to the same chamber $gC_+ = C_N = C'_M$. Thus the mapping $g \rightarrow gC_+$ is one to one which proves (i).

Choose a fundamental chamber C_+ and let S be the corresponding set of simple reflections generating W . A decomposition $g = s_1 \dots s_N, s_i \in S$ of $g \in W$ is called minimal if it is the shortest possible. Then $N = d(g)$ is the length of g and the distance $d(g, h)$ is defined by $d(g, h) = d(g^{-1}h)$. Denote gC_+ by C_g , $R(C_g)$ by $R(g)$ and $M_r(C_+)^{\pm}$ by M_r^{\pm} respectively. Identify the set of halfspaces M_r^{\pm} with $\hat{R} = R \times \{\pm 1\}$ and call elements $(r, \varepsilon) = \hat{r} \in \hat{R}$ the oriented reflections. A gallery C_0, \dots, C_N defines a sequence $(\hat{r}_1, \dots, \hat{r}_N)$ of oriented reflections by

$$(1) \quad \hat{r}_i = \begin{cases} (r_i, +1) & \text{if } C_i \subset M_r^+ \\ (r_i, -1) & \text{if } C_i \subset M_r^- \end{cases}$$

Denote by $\hat{r} \rightarrow g\hat{r}$ the action of W on \hat{R} corresponding to the natural action of W on the set of halfspaces. Define a function $\text{sgn}: W \times R \rightarrow \{\pm 1\}$ by

$$(2) \quad \text{sgn}(g, r) = \begin{cases} -1 & g \cdot r \in R(g) \\ 1 & g \cdot r \notin R(g) \end{cases}$$

and for $\hat{r} = (r, \varepsilon)$ set $-\hat{r} = (r, -\varepsilon)$.

COROLLARY 4.

- (i) For any $g, h \in W$, $d(g, h) = d(C_g, C_h)$ and $d(g) = |R(g)|$.
- (ii) $R(g) = \{r \in R: g^{-1}M_r^{\varepsilon} = M_{g^{-1}r}^{-\varepsilon}\}$.
- (iii) The action of W on \hat{R} is given by $g(r, \varepsilon) = (g \cdot r, \text{sgn}(g, r)\varepsilon)$.

Proof. (i) follows from Proposition 3 and Corollary 2. Recall that $R(g) = \{r \in R: C_g \subset M_r^-\}$. Since $g^{-1}C_g = C_+$ we have $g^{-1}M_r^- = M_{g^{-1}r}^+$. On the other hand if $r \notin R(g)$ then $C_g \subset M_r^+$ therefore $g^{-1}M_r^+ = M_{g^{-1}r}^+$ which proves (ii).

(ii) is equivalent to the assertion that $gM_r^{\varepsilon} = M_{g \cdot r}^{-\varepsilon}$ if $g \cdot r \in R(g)$ and $gM_r^{\varepsilon} = M_{g \cdot r}^{\varepsilon}$ if $g \cdot r \notin R(g)$ which proves (iii).

For $x \in M$ denote by $W_x \subset W$ the isotropy subgroup of x and by $R_x \subset R$ the set of $r \in R$ such that $rx = x$.

PROPOSITION 4.

- (i) Let $x, y \in C$, $g \in W$ and let $gx = y$. Then $x = y$ and $g \in W_x$.
 (ii) For any $x \in M$ the group W_x is generated by reflections $r \in R_x$.

Proof. Let C, D be such chambers that $C \cap D \neq \emptyset$. Since any wall $M_r \in R(C, D)$ separates C from D , it contains $C \cap D$. A minimal gallery $C = C_0, \dots, C_N = D$ going from C to D crosses only the walls $M_r \in R(C, D)$, thus every chamber C_0, \dots, C_N contains $C \cap D$ and reflections of the corresponding sequence (r_1, \dots, r_N) leave $C \cap D$ fixed pointwise. In the notation of (i), $y \in gC \cap C \neq \emptyset$. A minimal decomposition $g = s_1 \dots s_N$ corresponds to a minimal gallery going from C to gC and $g = r_N \dots r_1$. Thus g leaves $C \cap gC$ pointwise fixed, so $y = x$. For $x \in M$ let C be a chamber containing x . By the same argument as above any $g \in W_x$ is a product of $r_i \in R_x$ which proves (ii).

COROLLARY 5. The natural mapping $\phi: C_+ \rightarrow M/W$ is an isomorphism.

Proof. By Proposition 3, (i), ϕ is onto. By Proposition 4, (i) ϕ is one to one.

For $r, s \in R$ denote by $m(s, r) \in \{1, \dots, \infty\}$ the order of rs . Since $s^2 = 1$ for any $s \in R$ we have

- (i) $m(s, s) = 1$
 (3) (ii) $m(r, s) = m(s, r) \geq 2$ for $r \neq s$.

Definition 2 (cf. Bourbaki [2]). A Coxeter group is a group W with a finite set S of generators and a presentation

$$(4) \quad W = \langle S: (sr)^{m(s, r)} = 1, \quad r, s \in S \rangle$$

where the function $m: S \times S \rightarrow \{1, \dots, \infty\}$ satisfies (i) and (ii) above.

THEOREM 1. Let W be a reflection group acting on M , let C_+ be a fundamental chamber, let $S \subset R$ be the corresponding set of simple reflections and for $s, r \in S$ let $m(s, r)$ be the order of sr . Then W is a Coxeter group with the presentation

$$(5) \quad W = \langle S: (sr)^{m(s, r)} = 1 \rangle.$$

Proof. If C_0, \dots, C_N and C'_0, \dots, C'_M are two galleries such that $C'_0 = C_N$ we define their product by $C_0, \dots, C_N, C'_1, \dots, C'_M$. The inverse of the gallery

C_0, \dots, C_N is by definition C_N, \dots, C_0 . A loop is a closed gallery $C_0, \dots, C_N = C_0$. Any chamber of a loop can be taken for the starting chamber. If there are two loops passing through the same chamber C_0 , we define their product based on C_0 in an obvious way.

The dihedral group D_m is the Coxeter group of order $2m$ with the presentation

$$(6) \quad D_m = \langle s, r : s^2 = r^2 = (sr)^m = 1 \rangle.$$

It is isomorphic to the reflection group on \mathbf{R}^2 generated by reflections s, r in two lines meeting at the angle π/m .

By Proposition 3, (iv), there is a one to one correspondence between relations $s_1 \dots s_N = 1$, $s_i \in S$ and loops starting from C_+ .

If r, s are reflections in the walls of a chamber C , the group they generate is the dihedral group $D_{m(s,r)}$ and the defining relation $(rs)^{m(r,s)} = 1$ corresponds to the loop on \mathbf{R}^2 starting at C and going around the origin visiting every chamber once (see fig. 4). Let us call such loops elementary and let us call loops of the form $C_0, \dots, C_{N-1}, C_N, C_{N-1}, \dots, C_0$ trivial.

FIGURE 4

Loop corresponding to the relation $(rs)^3 = 1$

The statement of the Theorem is equivalent to the assertion that every loop is a product of elementary loops and trivial loops.

Let C_0, \dots, C_N be any gallery and set $d(C) = d(C, C_0)$. Then $d(C_{i+1}) = d(C_i) \pm 1$, $i = 0, \dots, N-1$ and if $C_N = C_0$, the graph of the function $d: i \rightarrow d(C_i)$ looks like graphs on fig. 5, a), b).

FIGURE 5 a), b)
Length function on loops

We call a loop perfect if it can not be decomposed into a product of shorter loops. It suffices to prove the assertion for perfect loops.

Assume that the function d has more than one local maximum. Thus $d(C_i)$ increases until $i = n_1$, $d(n_1) = n_1$, then decreases to a local minimum at $i = m_1 > n_1$, $d(m_1) = n_1 - (m_1 - n_1) = 2n_1 - m_1$, then starts increasing again. Let $C_0, C'_1, \dots, C'_{2n_1-m_1} = C_{m_1}$ be a minimal gallery going from C_0 to C_{m_1} . Then the original loop is the product of two loops

$$C_0, \dots, C_{n_1}, \dots, C_{m_1} = C_{2n_1-m_1}, C'_{2n_1-m_1-1}, \dots, C'_1, C_0$$

and

$$C_0, C'_1, \dots, C'_{2n_1-m_1} = C_{m_1}, C_{m_1+1}, \dots, C_N = C_0.$$

Each of them is shorter than the original one. Indeed, since the length of a loop is even, $N = 2M$ and $n_1 < M$ (see fig. 4, a)). The length of the first loop is $2n_1 < 2M$ and the length of the second is $(2n_1 - m_1) + (N - m_1) = N + 2(n_1 - m_1) < N$.

Thus the length function on a perfect loop must have a graph like one on fig. 4, b) no matter which chamber is used as a starting chamber.

Let $C_0, \dots, C_{2m} = C_0$ be a perfect loop and let (r_1, \dots, r_{2m}) be the corresponding reflection sequence. Since every subgallery of length m is

minimal, any reflection r that occurs in (r_1, \dots, r_{2m}) occurs twice. Moreover these m distinct reflections must occur in the order $r_1, \dots, r_m, r_1, \dots, r_m$ (see Proposition 2, (ii)). It is convenient to arrange the sequence $r_1, \dots, r_m, r_1, \dots, r_m$ as a circle (see fig. 6). Then it becomes clear that it does not matter which chamber is taken for the starting chamber and that a half of the sequence determines the other half.

FIGURE 6
Reflection sequence of a perfect loop

The relation corresponding to a perfect loop has the form

$$(6) \quad (r_m \dots r_1)^2 = 1.$$

Let $C_0, \dots, C_n, n \leq m$ be a subgallery of a perfect loop and assume that there is another minimal gallery $C_0, C'_1, \dots, C'_{n-1}, C_n$ going from C_0 to C_n (and different from $C_0, C_{2m-1}, \dots, C_{m+1}, C_m$ if $n = m$). Our loop is then the product of two loops

$$C_0, \dots, C_n, C'_{n-1}, \dots, C'_1, C_0 \quad \text{and} \quad C_0, C'_1, \dots, C'_{n-1}, C_n, C_{n+1}, \dots, C_0.$$

In the reflection sequence corresponding to the second loop the last m reflections are r_1, \dots, r_m but the first m are not r_1, \dots, r_m . So it is not perfect therefore the original loop was not perfect.

The argument above shows that every subgallery C_0, \dots, C_{m-1} of length $m - 1$ of a perfect loop of length $2m$ is unique, i.e. there is no other minimal gallery going from C_0 to C_{m-1} and the only other minimal gallery leading from C_0 to C_m is the other half of the loop.

Write $r_m \dots r_1$ as a product $s_1 \dots s_m$ of simple reflections. The word

$$(7) \quad s_1 \dots s_m s_1 \dots s_m = 1$$

has the cyclic property that $s_i = s_{m+i}$. Assume that the sequence s_1, \dots, s_m contains three distinct reflections. Then we can rewrite (7) as

$$(8) \quad s_3 s_1 s_2 \dots s_{m-1} s_3 s_1 s_2 \dots s_{m-1} = 1$$

where $s_3 \neq s_1 \neq s_2$. We will use the following

LEMMA 2 (compare with Bourbaki [2], ch. IV, § 1, Lemma 3). *If a word $s_1 \dots s_n$ is minimal and the word $s_1 \dots s_n s$ is not ($s \in S$) then there is $1 \leq i \leq n$ such that*

$$(9) \quad s_{i+1} \dots s_n s = s_i s_{i+1} \dots s_n$$

Proof of the Lemma. Let $1 \leq i \leq n$ be the maximal index such that $s_{i+1} \dots s_n s$ is minimal and $s_i s_{i+1} \dots s_n s$ is not. Consider the gallery $C_i, C_{i+1}, \dots, C_n, C$ corresponding by Proposition 1, (iv) to $s_i \dots s_n s$ and let r_i, \dots, r_n, r be the corresponding sequence of reflections. Since the gallery $C_i, C_{i+1}, \dots, C_n, C$ is not minimal and every subgallery of it is minimal, by Proposition 2, $r_i \neq r_{i+1} \neq \dots \neq r_n$ and $r = r_i$. Thus $s_i s_{i+1} \dots s_n s s_n \dots s_{i+1} s_i = s_i$ which implies $s_{i+1} \dots s_n s = s_i s_{i+1} \dots s_n$ and proves the Lemma.

The word $s_3 s_1 s_2 \dots s_{m-1} s_3$ is not minimal and every subword of it is minimal, therefore, by Lemma 2,

$$(10) \quad s_1 s_2 \dots s_{m-1} s_3 = s_3 s_1 s_2 \dots s_{m-1}$$

that is s_3 commutes with $s_1 s_2 \dots s_{m-1}$. This produces two relations

$$(11) \quad s_1 s_2 \dots s_{m-1} s_3 = s_3 s_1 s_2 \dots s_{m-1} = s_{m-1} \dots s_2 s_1 s_3$$

corresponding to three different galleries going from C_0 to C_m which contradicts to the assumption that the loop C_0, \dots, C_{2m} is perfect.

Thus (7) contains only two reflections s_1 and s_2 , i.e. it has the form

$$(12) \quad (s_1 s_2)^m = 1$$

which is one of the defining relations of the Coxeter group. This completes the proof of the Theorem.
