Scientists unlock sleep mysteries

A Lausanne University research team under Professor Mehdi Tafti has taken a step closer to answering a question that has baffled scientists for centuries – why do humans need to sleep?

Studying sleep deprivation in mice, the team has managed to determine what happens in the brain at the molecular level when asleep, and to isolate a gene that regulates sleep activity.

Mehdi Tafti, an expert in sleep disorders, has spent the past 20 years trying to work out why humans spend a third of their lives in bed. His research team recently published their findings in the *Proceedings of the National Academy of Science* journal, identifying a gene – Homer 1a – that controls levels of calcium in neurons in the brain.

Mice, like humans, need calcium to function when awake, but the longer they are up and about, the more calcium builds up, and when the levels get too high, the neurons get over-stimulated. Sleep, therefore, is nature's way of reducing these excessive calcium levels in the brain, and Homer 1a plays a key role. It regulates the levels of calcium to protect against hyperactivity of the brain. The more you stay awake, the more the gene Homer 1a is activated. It rings an alarm bell in your head and tries to counterbalance the build-up, warning: Be careful, calcium is trying to get in – you have to regulate it; otherwise it's going to be toxic.

In animal models, sleep deprivation is lethal; sleep deprived rats or mice die after two or three weeks. It has never been tested in humans but long-term sleep deprivation would probably lead to death.

Whether you are able to snooze until midday or wake up at the crack of dawn is all down to your genes, say experts. But what's the minimum amount of shut-eye we can get by on each night? The hypothesis is that there is a core amount of sleep that everybody needs, probably about five to six

hours. It's like food intake. You need a certain amount of food, but you know that everybody eats more than what we need.

Research shows that sleep-deprived individuals often have difficulty in responding to rapidly changing situations and making rational judgements. In real life situations, the consequences are grave. Lack of sleep is said to have been a contributory factor in a number of international disasters such as Exxon Valdez, Chernobyl, Three Mile Island and the Challenger shuttle explosion.

Sleep deprivation not only has a major impact on cognitive functioning but also on emotional and physical health. Disorders such as sleep apnoea which result in excessive daytime sleepiness have been linked to stress and high blood pressure. Research has also suggested that sleep loss may increase the risk of obesity because chemicals and hormones that play a key role in controlling appetite and weight gain are released during sleep. Lack of sleep has serious effects on our brain's ability to function. With continued lack of sufficient sleep, the part of the brain that controls language, memory, planning and sense of time is severely affected, practically shutting down.

There are also possible uses for treating people suffering from depression or schizophrenia. The scientists believe that there is a high chance the newly identified gene has an important influence on the sleeping disorders of people suffering from depression.

Contrary to what might first be imagined, sleep deprivation is an extremely potent anti-depressant. The problem is that it doesn't last long. When the patients go back to sleep they wake up depressed.

If this gene is removed in mice, they may have a depressive-like behaviour and if it is over-expressed you can treat the depression. Tests using humans are expected to start within the next four to five years.

Bird rules ruffle environmentalists' feathers

The Federal Environment Office has eased protection of the cormorant (called shag in New Zealand), a mid-sized bird that has been accused of plundering the catches of Swiss fishermen.

Cantons will be given greater freedom to control their shag populations, and some unhatched eggs may now be destroyed. The authorities said they had made the decision in consultation with all stakeholders, but the organisation BirdLife Switzerland argued that its concerns were ignored. It said valuable bird protection areas would now be threatened.

The shag – which feasts on only fish and small eels – has been breaking nets in search of food. As a result, fishermen have racked up considerable losses – SFr200'000 around Lake Neuchâtel alone – due to the thefts. *from swissinfo*
