(28.V.1996)

Abstract. In this article, we prove exponential localization for wide classes of Schrödinger operators, including those with magnetic fields, at the edges of unperturbed spectral gaps. We assume that the unperturbed operator $H_{0}$ has an open gap $I_{0} \equiv\left(B_{-}, B_{+}\right)$. The random potential is assumed to be Anderson-type with independent, identically distributed coupling constants. The common density may have either bounded or unbounded support. For either case, we prove that there exists an interval of energies in the unperturbed gap for which the almost sure spectrum of the family $H_{\omega} \equiv H_{0}+V_{\omega}$ is dense pure point with exponentially decaying eigenfunctions. We also prove that the integrated density of states is Lipschitz continuous in the unperturbed spectral gap $I_{0}$.

Key-Words: localization, random operators, Schrödinger operators

Dedicated to K. Hepp and W. Hunziker.

[^0]
## 1 Introduction

The phenomenon of exponential localization for various families of random Schrödinger operators $H_{\omega}=H_{0}+V_{\omega}$ on $L^{2}\left(\mathbb{R}^{d}\right), d \geq 1$, near the bottom of the almost sure spectrum is now reasonably well understood, see for example [5],[22], [20], [11], [12], [19], [24]. The results for lattice Schrödinger operators on $\ell^{2}\left(\mathbb{Z}^{d}\right)$ can be found in the book of Carmona and Lacroix [4] and Pastur and Figotin [27]. Recently, there have been several results [6], [23], [13], [14], [15], [31], [20], [1] concerning band edge localization, i.e. the existence of pure point spectra near the edges of the spectral bands of the deterministic, unperturbed operator $H_{0}$. In this paper, we prove that band edge localization is a rather general phenomenon. We study the perturbation of fixed, background Schrödinger operators $H_{0}=(-i \nabla-A)^{2}+V_{0}$ on $L^{2}\left(\mathbb{R}^{d}\right), d \geq 1$, with an open spectral gap $I_{0}=\left(B_{-}, B_{+}\right)$, by random potentials $V_{\omega}$ of Anderson-type

$$
\begin{equation*}
V_{\omega}(x)=\sum_{i \in \mathbb{Z}^{d}} \lambda_{i}(\omega) u(x-i) \tag{1.1}
\end{equation*}
$$

The coupling constants $\left\{\lambda_{i}(\omega) \mid i \in \mathbb{Z}^{d}\right\}$ are assumed to be independent and identically distributed with common density $h$. We assume $u \geq 0$ and supp $u$ is compact. There are three main results. First, we assume that supp $h$ is compact and that the almost sure spectrum $\Sigma$ of the family $H_{0}+V_{\omega}$ has an open spectral gap $\left(\tilde{B}_{-}, \widetilde{B}_{+}\right)$with $B_{-}<\tilde{B}_{-}<\tilde{B}_{+}<B_{+}$. We prove that near the band edges $\tilde{B}_{-}$and $\widetilde{B}_{+}$, the spectrum $\Sigma$ consists of only pure point spectrum with exponentially decaying eigenfunctions. This result requires that $h$ decays sufficiently rapidly near the edges of its support.

Secondly, we consider the case when $\operatorname{supp} h$ is unbounded so there is no spectral gap in $\Sigma$ near $I_{0}$. We add a coupling constant $g \geq 0$ and let $\Sigma(g)$ denote the deterministic spectrum of $H_{0}+g V_{\omega}$. For any energies $E_{ \pm}$with $B_{-}<E_{-}<E_{+}<B_{+}$, we prove that there exists $g_{0}>0$ such that $\Sigma(g) \cap\left(E_{-}, E_{+}\right)$is pure point for all $0<g<g_{0}$, with exponentially decaying eigenfunctions. Thirdly, we prove that the integrated density of states for each of the families $H_{\omega}$ and $H_{\omega}(g)$ is Lipschitz continuous in the spectral gap $I_{0}$ of $H_{0}$ in both cases.

In the case of bounded perturbations $V_{\omega}$, the localization result follows from the fact that the spectrum is "thin" near the band edges $\widetilde{B}_{ \pm}$(provided the density $h$ decays sufficiently rapidly). In fact, for local Hamiltonians $H_{\Lambda, \omega} \equiv H_{0}+\left(V_{\omega} \mid \Lambda\right)$, associated with bounded regions $\Lambda \subset \mathbb{R}^{d}$, we prove that the eigenvalues remain at a strictly positive distance from $\tilde{B}_{-}$ and $\widetilde{B}_{+}$with a good probability. This fact allows one to apply the Combes-Thomas argument [8] in order to prove decay estimates on the resolvent of $H_{\Lambda, \omega}$ with a good probability. This initial scale estimate, together with an improved Wegner estimate, are the starting points for the multiscale analysis of [5] which results in almost sure decay estimates for the localized resolvent of the infinite volume Hamiltonian. When the density $h$ has unbounded support, we must add a coupling constant $g$ and work in the weak coupling regime.

We also prove in this paper an improved version of the Combes-Thomas estimate [8] on the decay of localized resolvents. This result may be of independent interest. Suppose $H$ is a self-adjoint operator with a spectral gap $\left(B_{-}, B_{+}\right)$. The usual Combes-Thomas result gives an upper bound on the spatial decay of the resolvent $(H-E)^{-1}, E \in\left(B_{-}, B_{+}\right)$, with
a decay constant proportional to $\operatorname{dist}(E, \sigma(H))$. We prove here that the decay constant is proportional to $\sqrt{\Delta_{+}(E) \Delta_{-}(E)}$, where $\Delta_{+}(E) \equiv \operatorname{dist}\left(E,\left\{\lambda \in \sigma(H) \mid \lambda \geq B_{+}\right\}\right)$and $\Delta_{-}(E) \equiv$ $\operatorname{dist}\left(E,\left\{\lambda \in \sigma(H) \mid \lambda \leq B_{-}\right\}\right)$. Note that when $E$ is close to $\sigma(H)$, the decay is approximately [dist $(E, \sigma(H))]^{1 / 2}$. This is similar to the case when $E \leq \inf \sigma(H)$ and the decay constant is proportional to $[\operatorname{dist}(E, \sigma(H))]^{1 / 2}$.

In [23], Klopp studied localization induced by random perturbations of a periodic Schrödinger operator $H_{0}(h)=-h^{2} \Delta+V_{0}$ in the semiclassical regime. He proved exponential localization near the band edges of the first band of $H_{0}(h)$ for $h$ small. Figotin and Klein [13] studied band edge localization for perturbations of periodic lattice Schrödinger operators $H(g)=H_{0}+g v$, on $\ell^{2}\left(\mathbb{Z}^{d}\right)$, in the weak coupling regime. In [14], these results were extended to lattice models of acoustic and electromagnetic waves propagating in random media. These results for wave propagation were extended to continuum models in [15]. In all these cases, the random perturbation is Anderson-type. Aizenman [1] gave an elementary proof of band edge localization on the lattice in the weak disorder regime. He studied Anderson-type perturbations $H_{\omega}=H_{0}+\lambda V_{\omega}$, of a background operator $H_{0}=T+U_{0}$, where $T$ is a bounded self-adjoint operator with exponentially decaying matrix elements and $U_{0}$ is periodic. Aizenman proved that the a.s. spectrum of $H_{\omega}$ is pure point near $\sigma\left(H_{0}\right)$ for $\lambda$ in a certain regime of small values. He utilized an extension of the ideas of Aizenman and Molchanov [2] which avoids multiscale analysis (Unfortunately, it is not clear how to extend [2] to continuous models). Our own interest in band edge localization originated with our study of localization for the randomly perturbed Landau Hamiltonian on $L^{2}\left(\mathbb{R}^{2}\right)$ ([6], [3], [31], [11], [12]). We discuss this model in Example 2.1 of the next section.

This paper is organized as follows. In section 2, we present the main hypotheses and results. We provide several examples of models satisfying these hypotheses. An improved version of the Combes-Thomas estimate is presented in section 3. Section 4 contains a new proof of the Wegner estimate which can be applied to models with unbounded random potentials (see [3]). In section 5, we give estimates on the location of the spectrum of the finite-volume Hamiltonians $H_{\Lambda}$, with good probability. These results, with those of section 3 , allow us to verify the initial decay hypothesis $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ of [5]. By the multiscale analysis and perturbation theory of [5], we then establish band edge localization when supp $h$ is bounded. The case of supp $h$ unbounded is discussed in section 6 . We present certain technical trace ideal estimates in the appendix, section 7 .

## Acknowledgments

The authors want to thank E. Mourre for fruitful discussions about the decay estimates of section 3. We also thank B. Helffer, F. Klopp, W. Kirsch, A. Klein, S. Nakamura, and P. Stollman for stimulating discussions about various aspects of this paper. The authors gratefully acknowledge the hospitality of the Erwin Schrödinger Institute, Vienna, where part of this work was done.

## 2 The Models and the Main Results

We study random families of Schrödinger operators $H_{\omega}=H_{0}+V_{\omega}$ on $L^{2}\left(\mathbb{R}^{d}\right), d \geq 1$. The unperturbed Schrödinger operator $H_{0}$ has the form

$$
\begin{equation*}
H_{0}=(-i \nabla-A)^{2}+V_{0}, \tag{2.1}
\end{equation*}
$$

where $A$ is a vector potential and $V_{0}$ is a background electrostatic potential. We first list the assumptions on $H_{0}$ and present our main results. We then discuss the assumptions and give several examples. Let $R_{0}(z) \equiv\left(H_{0}-z\right)^{-1}$ denote the resolvent of $H_{0}$.
(H1) The operator $H_{0}$ is essentially self-adjoint on $C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$.
(H2) The spectrum of $H_{0}, \sigma\left(H_{0}\right)$, is semibounded and contains an open gap, that is, there exist finite constants $C_{0} \geq 0$ and $-C_{0} \leq B_{-}<B_{+} \leq \infty$ such that

$$
\sigma\left(H_{0}\right) \subset\left(-C_{0}, B_{-}\right] \cup\left[B_{+}, \infty\right)
$$

(H3) The operator $H_{0}$ is strongly locally compact in the sense that for any $f \in L^{\infty}\left(\mathbb{R}^{d}\right)$ with compact support, the operator $f\left(H_{0}+C_{0}+1\right)^{-1} \in \mathcal{J}_{q}$, for some even integer $q$, $1 \leq q<\infty$.
(H4) Let $\rho(x) \equiv\left(1+\|x\|^{2}\right)^{1 / 2}$. The operator

$$
H_{0}(\alpha) \equiv e^{i \alpha \rho} H_{0} e^{-i \alpha \rho}
$$

defined for $\alpha \in \mathbb{R}$, admits an analytic continuation as a type-A analytic family to a strip

$$
S\left(\alpha_{0}\right) \equiv\left\{x+i y \in \mathbb{C}| | y \mid<\alpha_{0}\right\}
$$

for some $\alpha_{0}>0$.

We now describe the random perturbations $V_{\omega}$. We assume $V_{\omega}$ is Anderson type of the form

$$
\begin{equation*}
V_{\omega}(x) \equiv \sum_{i \in \mathbb{Z}^{d}} \lambda_{i}(\omega) u(x-i) \tag{2.2}
\end{equation*}
$$

The coupling constants $\left\{\lambda_{i}(\omega)\right\}$ and the single-site potential $u$ are assumed to satisfy the following conditions.
(H5) The coupling constants $\left\{\lambda_{i}(\omega) \mid i \in \mathbb{Z}^{d}\right\}$ form a family of independent, identically distributed (iid) random variables. The common distribution has a density $h$ satisfying $0 \leq h \in L^{\infty}(\mathbb{R}) \cap C(\mathbb{R})$. There exist not necessarily finite, positive constants $0<m, M$ such that supp $h \subset[-m, M]$ and $h(0)>0$.
(H6) The density $h$ decays sufficiently rapidly near $-m$ and near $M$ in the following sense. If $0<m \leq M<\infty$, then

$$
\begin{aligned}
& 0<\mathbb{P}\{|\lambda+m|<\varepsilon\} \leq \varepsilon^{3 d / 2+\beta}, \\
& 0<\mathbb{P}\{|\lambda-M|<\varepsilon\} \leq \varepsilon^{3 d / 2+\beta},
\end{aligned}
$$

for some $\beta>0$. In the case that either $m$ or $M$ is infinite, we require that for some $r>\max (q, d / 2)$.

$$
C_{h} \equiv \sup _{\lambda} h(\lambda)|\lambda|^{r+2}<\infty
$$

We take $\Omega \equiv[\operatorname{supp} h]^{\mathbb{Z}^{d}}$ to be the probability space equipped with the probability measure $\mathbb{P}$ induced by the finite product measure. The single site potential $u$ in (2.2) is assumed to satisfy.
(H7) The single-site potential $u$ has compact support and $0 \leq u \in L^{\infty}\left(\mathbb{R}^{d}\right)$.

At the level of generality maintained so far, we need some hypotheses on the spectral properties of the random family $H_{\omega}$.
(H8) The family $\left\{H_{\omega} \mid \omega \in \Omega\right\}$ has deterministic spectrum $\Sigma$ in the sense that $\exists \Omega_{0} \subset \Omega$ with $\mathbb{P}\left(\Omega_{0}\right)=1$ such that for $\omega \in \Omega_{0}, \sigma\left(H_{\omega}\right)=\Sigma$.

According to whether supp $h$ is bounded or unbounded, we need to consider the nature of $\Sigma$ near the unperturbed spectral gap ( $B_{-}, B_{+}$).
(H9) Suppose supp $h$ is bounded, i.e. $0<m, M<\infty$. Then, $\exists$ constants $B_{ \pm}^{\prime}$ satisfying $B_{-}<B_{-}^{\prime}<B_{+}^{\prime}<B_{+}$such that

$$
\Sigma \cap\left\{\left(B_{-}, B_{-}^{\prime}\right) \cup\left(B_{+}^{\prime}, B_{+}\right)\right\} \neq \emptyset .
$$

We remark that in the presence of ergodicity (H8) is known (cf.[27]). In the unbounded case (H5) and (H7) imply that, the deterministic spectrum $\Sigma$ fills the gap ( $B_{-}, B_{+}$) entirely (see Proposition 6.4). Given (H9), we define the perturbed band edges $\widetilde{B}_{ \pm}$, satisfying $B_{-}<$ $\widetilde{B}_{-} \leq B_{-}^{\prime}$ and $B_{+}^{\prime} \leq \tilde{B}_{+}<B_{+}$by

$$
\begin{equation*}
\tilde{B}_{-} \equiv \sup \left\{E \in \Sigma \mid E \leq B_{-}^{\prime}\right\} \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\tilde{B}_{+} \equiv \inf \left\{E \in \Sigma \mid E \geq B_{+}^{\prime}\right\} \tag{2.4}
\end{equation*}
$$

We can now state our main results.

## Theorem 2.1

Assume (H1) - (H9) and that supph is bounded, i.e. $0<m, M<\infty$. There exist constants $E_{ \pm}$satisfying $B_{-} \leq E_{-}<\widetilde{B}_{-}$and $\tilde{B}_{+}<E_{+} \leq B_{+}$such that $\Sigma \cap\left(E_{-}, E_{+}\right)$is pure point with exponentially decaying eigenfunctions.

In the case that supp $h$ is unbounded, we must introduce a coupling constant $g$ and work in the weak disorder regime of small $g$.

## Theorem 2.2

Let $H_{\omega}(g) \equiv H_{0}+g V_{\omega}$. Suppose that supph is unbounded and assume the hypotheses (H1) - (H8). For any energies $E_{ \pm}$satisfying $B_{-}<E_{-}<E_{+}<B_{+}, \exists g_{0}=g_{0}\left(E_{ \pm}\right)>0$ such that for all $0<g<g_{0}$, we have $\Sigma \cap\left(E_{-}, E_{+}\right)$is pure point with exponentially decaying eigenfunctions.

Finally, the Wegner estimate of section 4 provides the following regularity result for the integrated density of states (IDS) in the unperturbed spectral gap.

## Theorem 2.3

Assume (H1) - (H9) and supph bounded or (Hi) - (H8) and supp h unbounded. In either case, the integrated density of states is Lipschitz continuous on $\left(B_{-}, B_{+}\right)$.

We remark that if $h \in C^{k}$, then we believe that the IDS $N(E) \in C^{k}\left(\left(B_{-}, B_{+}\right)\right)$. Such a result for $k \geq 3 d / 2$ would allow us to remove hypothesis (H6) in the case that supp $h$ is compact.

Let us make a few remarks on the hypotheses. We refer to the review of Simon[29] and the book by Cycon, Froese, Kirsch and Simon[9] for further details. A theorem of Leinfelder and Simader[25] states that if $V \in L_{l o c}^{2}, V_{-} \in K_{d}$, and $A \in L_{l o c}^{4}$, then $C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$ is a core for $H_{0}$, which is condition (H1). Let $H_{A} \equiv(-i \nabla-A)^{2}$ be the pure magnetic Hamiltonian. If $A \in C^{2}\left(\mathbb{R}^{d}, \mathbb{R}^{d}\right)$, it is easy to see (cf [29]) that $D\left(H_{A}\right) \subset H^{2}\left(\mathbb{R}^{d}\right)=D(-\Delta)$. Let us suppose also that $V_{0}$ is relatively $-\Delta$-bounded with relative bound $<1$. Then, $\left(-\Delta+V_{0}\right)$ is semibounded by some $-C_{0}>-\infty$. The diamagnetic inequality (see [29]) implies that $H_{0}$ is also semibounded with the same constant. The strong local compactness condition (H3) is immediate under these conditions. Indeed, it suffices to prove that for all $f \in L^{\infty}$ with compact support, the operator $f\left(-\Delta+C_{0}+1\right)^{-1} \in \mathcal{J}_{q}$, for all $q$ such that $\infty>q>[d / 2]$ as in (H3). This follows from the standard estimate (see [30]):

$$
f(x) g(-i \nabla) \in \mathcal{J}_{q} \quad \text { if } \quad f, g \in L^{q}\left(\mathbb{R}^{d}\right) \quad \text { for } \quad \infty>q>[d / 2]
$$

The analyticity condition (H4) is also satisfied for general $\left(A, V_{0}\right)$. For $\alpha \in \mathbb{R}$, we have

$$
H_{0}(\alpha) \equiv e^{i \alpha \rho} H_{0} e^{-i \alpha \rho}=H_{0}-2 \alpha \nabla \rho \cdot(-i \nabla-A)+i \alpha \Delta \rho+\alpha^{2}|\nabla \rho|^{2}
$$

with $|\nabla \rho|$ and $\Delta \rho$ bounded. Assuming that $V_{0}$ is relatively $H_{A}$-bounded, it suffices for analyticity in $\alpha$ to show that for some $z \in \rho\left(H_{A}\right)$, the operator

$$
\begin{equation*}
\left\{-2 \alpha \nabla \rho \cdot(-i \nabla-A)+i \alpha \Delta \rho+\alpha^{2}|\nabla \rho|^{2}\right\}\left(H_{A}-z\right)^{-1} \tag{2.5}
\end{equation*}
$$

is bounded with norm less than one for some $z \in \rho\left(H_{A}\right)$. Since the operator in (2.5) is bounded above by

$$
\operatorname{dist}\left(\sigma\left(H_{A}\right), z\right)^{-1}\left\{2|\alpha||\nabla \rho| \max \left\{1,|z|^{1 / 2}\right\}+|\alpha||\Delta \rho|+\alpha^{2}|\nabla \rho|^{2}\right\}
$$

it follows that for any fixed $\alpha_{0}>0$, this bound can be made $<1 / 2$ by taking $z=-i \sigma, \sigma>0$ sufficiently large. This shows that $H_{0}(\alpha)$ has a continuation to any strip $S\left(\alpha_{0}\right), \alpha_{0}>0$.

We now present several examples satisfying these conditions and hypotheses (H2), (H8) and (H9).

## Example 2.1

Landau Hamiltonians in $d=2$ dimensions. We take $V_{0}=0$ and $A=\frac{B}{2}\left(-x_{2}, x_{1}\right)$. In this case, the unperturbed spectrum of $H_{A}$ is pure point $\sigma\left(H_{A}\right)=\left\{E_{n}(B)=(2 n+1) B\right.$, $n=0,1,2, \ldots\}$. When supp $h$ is compact, the existence of localized states away from a region of size $\mathcal{O}\left(B^{-1}\right)$ centered at the Landau energies $E_{n}(B)$, and for $B$, large was proved in [6]. Theorem 2.1 applied to this case avoids the restriction that $B$ is large. The analog of Theorem 2.2, when supph is unbounded, is proved in [3].

## Example 2.2

Periodic Schrödinger Operators. We set $A=0$ so $H_{0}=-\Delta+V_{0}$ and assume that $V_{0}$ is a real, bounded, periodıc function with an open gap (see [28]). The random family $H_{\omega}$ has deterministic spectrum provided the lattice group of $V_{0}$ is commensurate with $\mathbb{Z}^{d}$. In the case of supp $h$ bounded, condition (H9) can be guaranteed by writing $H_{\omega}(\lambda)=H_{0}+\lambda V_{\omega}$ and taking $\lambda$ small enough.

## Example 2.3

Pure Magnetic Field Hamiltonians. We take $H_{0}=H_{A}(\lambda) \equiv(-i \nabla-\lambda A)^{2}$ with $\lambda \in \mathbb{R}$, and $A \in C^{1}\left(\mathbb{R}^{d}, \mathbb{R}^{d}\right)$. Amongst other questions, Hempel and Herbst [17] studied the case when the magnetic field $B=d A$ is periodic with respect to $\mathbb{Z}^{d}(d \geq 2)$. Let $M_{B} \equiv\{x \mid B(x)=0\}$ and $M_{A} \equiv\{x \mid A(x)=0\}$. Under the condition that $\left|M_{B} \backslash M_{A}\right|=0$, they show that $H_{A}(\lambda)$ converges in the norm resolvent sense as $\lambda \rightarrow \infty$ to the Dirichlet Laplacian on M. Based on this, they construct examples of pure magnetic hamiltonians $H_{A}(\lambda)$ in dimensions $d \geq 2$ with periodic magnetic fields and with open spectral gaps for all $\lambda$ sufficiently large. As discussed above, our hypotheses hold for these models.

## Example 2.4

Magnetic Hamiltonians with periodic Potentials. Nakamura [26] (inspired by [17]) studied the existence of open spectral gaps for more general magnetic Schrödinger operators, for $d \geq 2$, of the form

$$
H_{0}(\lambda)=(-i \nabla-\lambda A)^{2}+V_{0},
$$

with $A \in C^{1}\left(\mathbb{R}^{d}, \mathbb{R}^{d}\right)$ and $V_{0}$ real and bounded. The result of [26] of interest to us is the following. Suppose $B=d A$ and $V$ are periodic with respect to a lattice subgroup $\Gamma$ of $\mathbb{Z}^{d}$ with bounded fundamental domain $\Omega_{\Gamma}$. Let $H_{0}^{D}(\lambda)$ be the restriction of $H_{0}(\lambda)$ to $\Omega_{\Gamma}$ with Dirichlet boundary conditions on $\partial \Omega_{\Gamma}$. The spectrum $\Sigma(\lambda)$ of $H_{0}^{D}(\lambda)$ is discrete. Under the assumption that the largest eigenvalue of the matrix $\left(B_{i j}(x)\right)$ restricted to $\partial \Omega_{\Gamma}$ is strictly positive, Nakamura proves that for all $\lambda$ large $\sigma\left(H_{0}(\lambda)\right)$ lies in neighborhoods of size $\mathcal{O}\left(e^{-\alpha \sqrt{\lambda}}\right)$, for some $\alpha>0$, about $\Sigma(\lambda)$. Hence, there are open spectral gaps in $\sigma\left(H_{0}(\lambda)\right)$ and Theorems 2.1 and 2.2 apply to random perturbations of these operators. Note that if $A$ is periodic, the operator $H_{0}(\lambda)$ has band spectrum and the width of the bands is $\mathcal{O}\left(e^{-\alpha \lambda}\right)$.

## Example 2.5

Combes-Hislop model revisited. Theorem 2.1 can be applied to the Anderson type models studied in [5] improving the result proven there. Let $H_{\omega} \equiv-\Delta+V_{\omega}$, where $V_{\omega}$ is given in (2.2). In [5], we assumed (H5) with $m=0, M<\infty$, and that $u \geq C_{0} \chi_{\Lambda_{0}}$, where $\chi_{\Lambda_{0}}$ is the characteristic function on the unit cube. The present work allows us to remove this last assumption on the single-site potential $u$. We choose a constant $C_{1}>0$ satisfying $C_{1}<M$ and write

$$
\begin{align*}
H_{\omega} & =\left\{-\Delta+\sum_{i \in \mathbb{Z}^{d}} C_{1} u_{i}\right\}+\sum_{i \in \mathbb{Z}^{d}}\left(\lambda_{i}-C_{1}\right) u_{i} \\
& =H_{0}+\tilde{V}_{\omega} \tag{2.6}
\end{align*}
$$

where $u_{i}(x) \equiv u(x-i)$. The operator $H_{0}$ is a periodic Schrödinger operator with a positive potential. and hence $\inf \sigma\left(H_{0}\right)=\Sigma_{0}>0$. The potential $\tilde{V}_{\omega}$ is an Anderson-type potential with coupling constants $\tilde{\lambda}_{i}(\omega) \equiv \lambda_{i}(\omega)-C_{1}$. The density of these random variables has support in $\left[-C_{1}, M-C_{1}\right]$. Theorem 2.1 now shows that there is a small interval of energy of the form $\left[0, E_{0}\right]$, for some $E_{0}>0$, in which the spectrum is pure pont almost surely. Theorem 2.3 guarantees the Lipschitz continuity of the integrated density of states in the interval $\left[0, \Sigma_{0}\right]$.

## 3 Improved Resolvent Decay Estimates

In this section, we present an alternative form of the Combes-Thomas method [8] which allows an improvement on the rate of decay of the resolvent which is of independent interest. The basic technical result is the following.

## Lemma 3.1

Let $A$ and $B$ be two self-adjoint operators such that $d_{ \pm} \equiv \operatorname{dist}\left(\sigma(A) \cap \mathbb{R}^{ \pm}, 0\right)>0$, and $\|B\|<1$. Then,
(i) For $\beta \in \mathbb{R}$ s.t. $|\beta|<\frac{1}{2} \sqrt{d_{+} d_{-}}$, one has $0 \in \rho(A+i \beta B)$,
(ii) For $\beta \in \mathbb{R}$ as in (i),

$$
\left\|(A+i \beta B)^{-1}\right\| \leq 2 \sup \left(d_{+}^{-1}, d_{-}^{-1}\right)
$$

## Proof:

Let $P_{ \pm}$be the spectral projectors for $A$ corresponding to the sets $\sigma(A) \cap \mathbb{R}^{ \pm}$, respectively and define $u_{ \pm} \equiv P_{ \pm} u$. By the Schwarz inequality one has

$$
\begin{align*}
\|u\|\|(A+i \beta B) u\| & \geq \operatorname{Re}\left\langle\left(u_{+}-u_{-}\right),(A+i \beta B)\left(u_{+}+u_{-}\right)\right\rangle \\
& \geq d_{+}\left\|u_{+}\right\|^{2}+d_{-}\left\|u_{-}\right\|^{2}-2 \beta \operatorname{Im}\left\langle u_{+}, B u_{-}\right\rangle  \tag{3.1}\\
& \geq \frac{1}{2}\left(d_{+}\left\|u_{+}\right\|^{2}+d_{-}\left\|u_{-}\right\|^{2}\right),
\end{align*}
$$

where we again used the Schwarz inequality to estimate the inner product. It follows that

$$
\|(A+i \beta B) u\| \geq \frac{1}{2} \min \left(d_{+}, d_{-}\right)\|u\|
$$

and since this is independent of the sign of $\beta$, the lemma follows.

## Proposition 3.2

Let $\widetilde{H}$ be a semibounded self-adjoint operator with a spectral gan $G \equiv\left(F_{-}, F_{+}\right) \simeq \rho(\widetilde{H})$. Let $W$ be a symmetric operator such that $D(W) \supset D\left(\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}}\right)$ and $\|\left(\widetilde{H}+C_{0}\right)^{-\frac{1}{2}} W(\widetilde{H}+$ $\left.C_{0}\right)^{-\frac{1}{2}} \|<1$, for some $C_{0}$ such that $\widetilde{H}+C_{0}>1$. For any $E \in G$, let $\Delta_{ \pm} \equiv \operatorname{dist}\left(E_{ \pm}, E\right)$. Then, we have
(i) The energy $E \in \rho(\widetilde{H}+i \beta W)$ for all real $\beta$ satisfying

$$
|\beta|<\frac{1}{2}\left\{\frac{\Delta_{+} \Delta_{-}}{\left(E_{+}+C_{0}\right)\left(E_{-}+C_{0}\right)}\right\}^{\frac{1}{2}}
$$

(ii) for any real $\beta$ and energy $E$ as in (i),

$$
\left\|(\widetilde{H}+i \beta W-E)^{-1}\right\| \leq 2 \sup \left(\frac{E_{+}+C_{0}}{\Delta_{+}}, \frac{E_{-}+C_{0}}{\Delta_{-}}\right)
$$

## Proof:

Let $E \in G$ and $C_{0}$ be as above. Define a self-adjoint operator $A \equiv\left(\widetilde{H}+C_{0}\right)^{-1}(\widetilde{H}-E)$ and $B \equiv\left(\widetilde{H}+C_{0}\right)^{-\frac{1}{2}} W\left(\widetilde{H}+C_{0}\right)^{-\frac{1}{2}}$. By hypothesis, the operator $B$ is self-adjoint and satisfies $\|B\|<1$. Note that $0 \in \rho(A)$ and

$$
\begin{equation*}
d_{ \pm} \equiv \operatorname{dist}\left(\sigma(A) \cap \mathbb{R}^{ \pm}, 0\right)=\Delta_{ \pm}\left(E_{ \pm}+C_{0}\right)^{-1}>0 \tag{3.2}
\end{equation*}
$$

Applying Lemma 3.1 to these operators $A$ and $B$, we see that for $\beta$ as in (i), $0 \in \rho(A+i \beta B)$ and that

$$
\left\|(A+i \beta B)^{-1}\right\| \leq 2 \sup \left(\frac{E_{+}+C_{0}}{\Delta_{+}}, \frac{E_{-}+C_{0}}{\Delta_{-}}\right)
$$

Let $P_{ \pm}$be as in the proof of Lemma 3.1. For any $w \in D(\widetilde{H})$,

$$
\begin{aligned}
\|(\widetilde{H}+i \beta W-E) w\| & =\left\|\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}}(A+i \beta B)\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\| \\
& \geq\left\|(A+i \beta B)\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\|
\end{aligned}
$$

since $\left(\widetilde{H}+C_{0}\right) \geq 1$. We now repeat estimate (3.1) taking $u \equiv\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w$. This gives

$$
\begin{align*}
\|(\widetilde{H}+i \beta W-E) w\| \geq & \frac{1}{2}\left\|\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} u\right\|^{-1}\left(d_{+}\left\|P_{+}\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\|^{2}\right. \\
& +\left(d_{-}\left\|P_{-}\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\|^{2}\right)  \tag{3.3}\\
\geq & \frac{1}{2} \min \left(d_{+}, d_{-}\right)\left\|\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\|
\end{align*}
$$

Since $\left\|\left(\widetilde{H}+C_{0}\right)^{\frac{1}{2}} w\right\| \geq\|w\|$ and $d_{ \pm}$are defined in (3.2), result (ii) follows from (3.3) and Lemma 3.1.

Theorem 3.3 Let $H_{0}$ be given as in (2.1) satisfying (H1) and (H4). Let $V$ be $H_{0}$-bounded with relative bound less than 1 and define the self-adjoint operator $H=H_{0}+V$. Then the dilated operator $H(\alpha) \equiv e^{i \alpha \rho} H e^{-i \alpha \rho}, \alpha \in \mathbb{R}$, admits an analytic continuation to a type- $A$ family on the strip $S\left(\alpha_{0}\right)$ ( $\rho$ and $S\left(\alpha_{0}\right)$ are defined in (H4)). Suppose $H_{0}$ satisfies (H2) and that $H$ has a spectral gap $G \equiv\left(E_{-}, E_{+}\right) \subset\left(B_{-}, B_{+}\right)\left(E_{-} \neq E_{+}\right)$. For $E \in G$, define $\Delta_{ \pm} \equiv \operatorname{dist}\left(E_{ \pm}, E\right)$. Then there exist finite constants $C_{1}, C_{2}>0$, depending only on $H_{0}$ and $V$, such that
(i) for any real $\beta$ satisfying $|\beta|<\min \left(\alpha_{0}, C_{1} \sqrt{\Delta_{+} \Delta_{-}}, \sqrt{\Delta_{+} / 2}\right)$, the energy $E \in \rho(H(i \beta))$;
(ii) for any real $\beta$ as in (i),

$$
\begin{equation*}
\left\|(H(i \beta)-E)^{-1}\right\| \leq C_{2} \max \left(\Delta_{+}^{-1}, \Delta_{-}^{-1}\right) \tag{3.4}
\end{equation*}
$$

## Proof:

As in the discussion of (H4) in section 2, we have,

$$
H(\alpha)=H+\alpha^{2}|\nabla \rho|^{2}+\alpha W,
$$

where $\alpha \in \mathbb{R}$ and $W=-(\nabla \rho \cdot(p-A)+(p-A) . \nabla \rho)$ is symmetric. Note that $\|\nabla \rho\|_{\infty}=1$ and $\|\Delta \rho\|_{\infty}=1$ and that $V$ and $V_{0}$ are relatively $(p-A)^{2}$-bounded. Consequently, (2.1) is less than $1 / 2$ for $|\operatorname{Imz}|$ large enough. This proves analyticity of $H(\alpha)$ in $S\left(\alpha_{0}\right)$. Taking $\alpha=i \beta, \beta$ real and $|\beta|<\alpha_{0}$, we have

$$
H(i \beta)=H-\beta^{2}|\nabla \rho|^{2}+i \beta W .
$$

We apply Proposition 3.2 to this operator taking $\widetilde{H} \equiv H-\tilde{\tilde{E}}^{2}|\nabla \rho|^{2}$. This operator has a spectral gap which contains $\left(\widetilde{E}_{-}, \tilde{E}_{+}\right)$, where $\tilde{E}_{-}=E_{-}$and $\widetilde{E}_{+}=E_{+}-\beta^{2}$. In order that $\tilde{\Delta}_{+} \equiv \operatorname{dist}\left(\tilde{E}_{+}, E\right)>\left(\Delta_{+} / 2\right)$, we require $|\beta|<\sqrt{\Delta_{+} / 2}$. (Note that $\tilde{\Delta}_{-}=\Delta_{-}$). We can now apply Proposition 3.2 to conclude $E \in \rho(H(i \beta))$ for $|\beta|<\min \left\{\alpha_{0}, C_{1} \sqrt{\Delta_{+} \Delta_{-}}, \sqrt{\Delta_{+} / 2}\right\}$ and that (3.4) holds.

## 4 The Wegner Estimate

In this section, we prove a Wegner estimate for local Hamiltonians valid at all energies in the spectral gap of $H_{0}$. This estimate holds in the case of unbounded potentials as will be discussed in section 6 (see also [3] for an application of this estimate to 2-dimensional Landau Hamiltonians with unbounded potentials). Let $\Lambda \subset \mathbb{R}^{d}$ be a bounded region and denote by $H_{\Lambda, \omega}=H_{0}+\left(V_{\omega} \mid \Lambda\right)$. Since $\left(V_{\omega} \mid \Lambda\right)$ is a relatively compact perturbation of $H_{0}$, the spectrum $\sigma\left(H_{\Lambda, \omega}\right) \cap\left(B_{-}, B_{+}\right)$is discrete. Let $\mathbb{P}_{\Lambda}$ and $\mathbb{E}_{\Lambda}$ denote the probability and expectation with respect to the random variables associated with $\Lambda \cap \mathbb{Z}^{d} \equiv \tilde{\Lambda}$. We denote by $\operatorname{Tr}$ the trace on $L^{2}\left(\mathbb{R}^{d}\right)$. Let $R_{\Lambda}(z)$ and $E_{\Lambda}($.$) denote the resolvent and the spectral projection for H_{\Lambda, \omega}$ respectively; we often suppress the $\omega$ and write $H_{\Lambda}$ for $H_{\Lambda, \omega}, V_{\Lambda}$ for $\left(V_{\omega} \mid \Lambda\right)$, and $R_{0}(z)$ for $\left(H_{0}-z\right)^{-1}$.

## Theorem 4.1

Assume (H1) - (H3), (H5) and (H7) - (H8). For any $E_{0} \in\left(B_{-}, B_{+}\right)$and for any $\eta<\frac{1}{2} \operatorname{dist}\left(E_{0}, \sigma\left(H_{0}\right)\right), \exists$ finite constant $C_{E_{0}}$, depending on $\left[\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)\right]^{-1}$ such that:

$$
\begin{equation*}
\mathbb{P}_{\Lambda}\left\{\operatorname{dist}\left(\sigma\left(H_{\Lambda, \omega}\right), E_{0}\right)<\eta\right\} \leq C_{E_{0}} \eta|\Lambda| \tag{4.1}
\end{equation*}
$$

## Proof:

Let $I_{\eta}=\left[E_{0}-\eta, E_{0}+\eta\right]$. We write $H_{\Lambda}$ for $H_{\Lambda, \omega}, V_{\Lambda}$ for $\left(V_{\omega} \mid \Lambda\right)$ and $R_{0}$ for $R_{0}\left(E_{0}\right)$. By Chebishev's inequality the left hand side of (4.1) is bounded above by

$$
\mathbb{E}_{\Lambda}\left(\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right)\right)
$$

To control the trace, we recall that any eigenfunction $\psi_{E}$ of $H_{\Lambda} \psi_{E}=E \psi_{E}, E \in I_{\eta}$, satisfies

$$
\begin{equation*}
K_{0} \psi_{E}=-\psi_{E}+R_{0}\left(H_{\Lambda}-E_{0}\right) \psi_{E} \tag{4.2}
\end{equation*}
$$

where $K_{0} \equiv R_{0} V_{\Lambda}$. From (4.2), it follows easily that:

$$
\begin{equation*}
E_{\Lambda}\left(I_{\eta}\right)=-K_{0} E_{\Lambda}\left(I_{\eta}\right)+R_{0}\left(H_{\Lambda}-E_{0}\right) E_{\Lambda}\left(I_{\eta}\right) \tag{4.3}
\end{equation*}
$$

Hence, noting that $E_{\Lambda}\left(I_{\eta}\right)$ is a positive trace class operator,

$$
\begin{aligned}
\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right) & =\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{1} \\
& \leq\left|\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\right)\right|+\eta\left\|R_{0}\right\|\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}
\end{aligned}
$$

and by the assumption on $\eta$ :

$$
\begin{equation*}
\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right) \leq 2\left|\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\right)\right| \tag{4.4}
\end{equation*}
$$

A first consequence of (4.4) is, by the Hölder inequality:

$$
\begin{aligned}
\mathbb{E}_{\Lambda}\left(\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}\right) & \leq 2 \mathbb{E}_{\Lambda}\left(\left\|K_{0} E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}\right) \\
& \leq 2 \mathbb{E}_{\Lambda}\left(\left\|K_{0}\right\|_{q}\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{p}\right) \quad\left(\frac{1}{q}+\frac{1}{p}=1\right) \\
& \leq 2\left\{\mathbb{E}_{\Lambda}\left(\left\|K_{0}\right\|_{q}^{q}\right)\right\}^{(1 / q)}\left\{\mathbb{E}_{\Lambda}\left(\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{p}^{p}\right)\right\}^{(1 / p)}
\end{aligned}
$$

where $\left\|\|_{q}\right.$ denote the norm in the Schatten class $\mathcal{J}_{q}$. By Proposition 7.4 and the fact that $\mathbb{E}_{\Lambda}\left(\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{p}^{p}\right)=\mathbb{E}_{\Lambda}\left(\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}\right.$, since all the eigenvalues of the spectral projector are equal to one, we obtain,

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left(\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}\right) \leq 2 C|\Lambda| \tag{4.5}
\end{equation*}
$$

from which the existence of the integrated density of states, for energies in the unperturbed spectral gap, follows. Now, we use the adjoint of formula (4.3) to derive

$$
K_{0} E_{\Lambda}\left(I_{\eta}\right)=-K_{0} E_{\Lambda}\left(I_{\eta}\right) K_{0}^{\star}+K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(H_{\Lambda}-E_{0}\right) R_{0}
$$

which implies

$$
\begin{aligned}
\left|\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\right)\right| & \leq\left\|K_{0} E_{\Lambda}\left(I_{\eta}\right)\right\|_{1} \\
& \leq \operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right) K_{0}^{\star}\right)+\eta\left\|R_{0}\right\|\left\|K_{0} E_{\Lambda}\left(I_{\eta}\right)\right\|_{1}
\end{aligned}
$$

Hence, by (4.4),

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left(\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right) \leq 4 \mathbb{E}_{\Lambda}\left(\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right) K_{0}^{\star}\right)\right.\right. \tag{4.6}
\end{equation*}
$$

If $q>2$, one continues this procedure and writes:

$$
\begin{equation*}
K_{0} E_{\Lambda}\left(I_{\eta}\right) K_{0}^{\star}=-K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(K_{0}^{\star}\right)^{2}+K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(H_{\Lambda}-E\right) R_{0} K_{0}^{\star} \tag{4.7}
\end{equation*}
$$

One has by Hölder's inequality,

$$
\begin{align*}
\left|\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(H_{\Lambda}-E_{0}\right) R_{0} K_{0}^{\star}\right)\right| & =\left\|K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(H_{\Lambda}-E_{0}\right) R_{0} K_{0}^{\star}\right\|_{1} \\
& \leq \eta\left\|R_{0}\right\|\left\|K_{0} E_{\Lambda}\left(I_{\eta}\right)\right\|_{q /(q-1)}\left\|K_{0}^{\star}\right\|_{q} \\
& \leq \eta\left\|R_{0}\right\|\left\|K_{0}\right\|_{q}^{2}\left\|E_{\Lambda}\left(I_{\eta}\right)\right\|_{q /(q-2)} . \tag{4.8}
\end{align*}
$$

Taking the expectation and again using Hölder's inequality, Proposition 7.4, and (4.5), one can bound the expectation of the left hand side of (4.8) by:

$$
(2 C)^{\frac{q-2}{q}} \eta\left\|R_{0}\right\||\Lambda| .
$$

Consequently, equations (4.6)-(4.8) imply

$$
\begin{aligned}
\mathbb{E}_{\Lambda}\left(\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right) \leq\right. & 4 \mathbb{E}_{\Lambda}\left(\mid \operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(K_{0}^{\star}\right)^{2} \mid\right)\right. \\
& +4(2 C)^{\frac{q-2}{q}} \eta \operatorname{dist}\left(E_{0}, \sigma\left(H_{0}\right)\right)^{-1}|\Lambda|
\end{aligned}
$$

If $q>3$, one repeats this procedure again. Finally, one obtains:

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left(\operatorname{Tr}\left(E_{\Lambda}\left(I_{\eta}\right)\right) \leq 4 \mathbb{E}_{\Lambda}\left(\left|\operatorname{Tr}\left(K_{0} E_{\Lambda}\left(I_{\eta}\right)\left(K_{0}^{\star}\right)^{q-1} \mid\right)+\tilde{C} \eta \operatorname{dist}\left(E_{0}, \sigma\left(H_{0}\right)\right)^{-1}\right| \Lambda \mid\right.\right. \tag{4.9}
\end{equation*}
$$

where $\tilde{C}$ depends on $q$ and the constant $C$ of Proposition 7.4.
To estimate the first term on the right hand side of (4.9), we expand the potential $V_{\Lambda}=\sum_{i \in \tilde{\Lambda}} \lambda_{i} u_{i}$, where $u_{i}(x) \equiv u(x-i)$. For each q-tuple of indices $\{i\} \equiv\left(i_{1}, \ldots, i_{q}\right) \in \tilde{\Lambda}^{q}$, we define:

$$
\begin{equation*}
K_{i_{1} \ldots i_{q}} \equiv u_{i_{2}}^{\frac{1}{2}} R_{0} u_{i_{3}} R_{0} u_{i_{4}} \ldots . u_{i_{q}} R_{0}^{2} u_{i_{1}}^{\frac{1}{2}} \tag{4.10}
\end{equation*}
$$

We prove in the appendix, section 7 , that (H3) implies that $K_{\{i\}} \equiv K_{i_{1} \ldots i_{q}} \in \mathcal{J}_{1}$. In terms of this operator, the first term on the right side of (4.9) becomes

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left\{\sum_{i_{1}, \ldots i_{q} \in \tilde{\Lambda}} \lambda_{i_{1}}(\omega) \ldots \lambda_{i_{q}}(\omega) \operatorname{Tr}\left\{K_{\{i\}}\left(u_{i_{1}}^{\frac{1}{2}} E_{\Lambda}\left(I_{\eta}\right) u_{i_{2}}^{\frac{1}{2}}\right)\right\}\right\} . \tag{4.11}
\end{equation*}
$$

Since $K_{\{i\}}$ is compact, we write it in terms of its singular value decomposition. For each multi-index $\{i\}$, there exists a pair of orthonormal bases, $\left\{\phi_{k}^{\{i\}}\right\}$ and $\left\{\psi_{k}^{\{i\}}\right\}$, and nonnegative numbers $\left\{\mu_{k}^{\{i\}}\right\}$, all independent of $\omega$, such that

$$
\begin{equation*}
K_{\{i\}}=\sum_{k=1}^{\infty} \mu_{k}^{\{i\}}\left|\phi_{k}^{\{i\}}\right\rangle\left\langle\psi_{k}^{\{i\}}\right| . \tag{4.12}
\end{equation*}
$$

Inserting the representation (4.12) into (4.11) and expanding the trace in $\left\{\phi_{k}^{\{i\}}\right\}$, we obtain

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left\{\sum_{\{i\} \in \tilde{\Lambda}^{q}} \sum_{k \geq 1} \lambda_{\{i\}}(\omega) \mu_{k}^{\{i\}}\left\langle\psi_{k}^{\{i\}},\left(u_{i_{1}}^{\frac{1}{2}} E_{\Lambda}\left(I_{\eta}\right) u_{i_{2}}^{\frac{1}{2}}\right) \phi_{k}^{\{i\}}\right\rangle\right\}, \tag{4.13}
\end{equation*}
$$

where $\lambda_{\{i\}}(\omega) \equiv \lambda_{i_{1}}(\omega) \ldots \lambda_{i_{q}}(\omega)$. Recalling that $E_{\Lambda}\left(I_{\eta}\right) \geq 0$, we bound the $k$-sum above by:

$$
\begin{align*}
& \frac{1}{2} \sum_{k \geq 1} \mu_{k}^{\{i\}} \mathbb{E}_{\Lambda}\left\{\left|\lambda_{\{i\}}(\omega)\right|\left\langle\psi_{k}^{\{i\}},\left(u_{i_{1}}^{\frac{1}{2}} E_{\Lambda}(I \eta) u_{i_{1}}^{\frac{1}{2}}\right) \psi_{k}^{\{i\}}\right\rangle\right.  \tag{4.14}\\
&+\left.\left|\lambda_{\{i\}}(\omega)\right|\left\langle\phi_{k}^{\{i\}},\left(u_{i_{2}}^{\frac{1}{2}} E_{\Lambda}(I \eta) u_{i_{2}}^{\frac{1}{2}}\right) \phi_{k}^{\{i\}}\right\rangle\right\}
\end{align*}
$$

From independance of the $\lambda_{i}$ 's, the spectral averaging result (see [5] or [7]) applied to each term in (4.14) gives for the first term:

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left\{\left|\lambda_{\{i\}}(\omega)\right|\left\langle\psi_{k}^{\{i\}},\left(u_{i_{1}}^{\frac{1}{2}} E_{\Lambda}\left(I_{\eta}\right) u_{i_{1}}^{\frac{1}{2}}\right) \psi_{k}^{\{i\}}\right\rangle\right\} \leq C_{1} \eta \tag{4.15}
\end{equation*}
$$

where $C_{1}$ is finite according to (H6). From (4.13)-(4.15), we obtain an upper bound for the first term on the right hand side of (4.9),

$$
\begin{equation*}
C_{1}^{\prime} \eta \sum_{i_{1}, \ldots, i_{q} \in \tilde{\Lambda}}\left(\left\|K_{\{i\}}\right\|_{1}\right) \tag{4.16}
\end{equation*}
$$

In the appendix, we prove in Proposition 7.2 that $\exists$ finite constant $C_{E_{0}}>0$, depending only on $\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)^{-1}$ and the dimension $d \geq 1$, such that (4.16) is bounded above by

$$
\begin{equation*}
C_{1}^{\prime} C_{E_{0}} \eta|\Lambda| \tag{4.17}
\end{equation*}
$$

Results (4.9) and (4.17) prove the theorem.

## 5 Verification of [H1] $\left(\gamma_{0}, \ell_{0}\right)$

The goal of this section is to prove the hypothesis $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ for finite volume Hamiltonians corresponding to the models introduced in section 2 . We let $\Lambda \subset \mathbb{R}^{d}$ denote a bounded open region and $\Lambda_{\ell}\left(x_{0}\right) \equiv\left\{x \in \mathbb{R}^{d} \| x_{i}-x_{0, i} \mid<\ell / 2, i=1, \ldots, d\right\}$. When $x_{0}=0$, we will write $\Lambda_{\ell}$ for simplicity. The potential depending only on the $\lambda_{i}$ in a region $\Lambda$ is denoted $V_{\Lambda, \omega}=\left(V_{\omega} \mid \Lambda\right)$.The finite volume Hamiltonians $H_{\Lambda, \omega}$ are defined as $H_{\Lambda, \omega} \equiv H_{0}+V_{\Lambda, \omega}$. Since $V_{\Lambda, \omega}$ has compact support, it is a relatively compact pertubation of $H_{0}$ and hence $\sigma_{\text {ess }}\left(H_{0}\right)=\sigma_{\text {ess }}\left(H_{\Lambda, \omega}\right)$. One of our first tasks is to locate precisely the eigenvalues of $H_{\Lambda, \omega}$ in the gap ( $B_{-}, B_{+}$) with good probability.

The condition $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ on the resolvent of $H_{\Lambda, \omega}$, written $R_{\Lambda}(z)=\left(H_{\Lambda, \omega}-z\right)^{-1}$, when it exists, is the following. For any $\chi \in C^{2}$, define the first order differential operator $W(\chi)$ by

$$
\begin{equation*}
W(\chi) \equiv[-\Delta, \chi]=-\nabla \cdot \nabla \chi-\nabla \chi \cdot \nabla \tag{5.1}
\end{equation*}
$$

This operator is localized on the support of $\nabla \chi$. Fix any $\delta>0$ small and let $\Lambda_{\ell, \delta} \equiv\{x \in$ $\left.\Lambda_{\ell} \mid \operatorname{dist}\left(\partial \Lambda_{\ell}, \chi\right)>\delta\right\}$. We will use $\chi_{\ell}$ to denote a function satisfying $\chi_{\ell} \mid \Lambda_{\ell, \delta}=1, \operatorname{supp} \chi_{\ell} \subset \Lambda_{\ell}$
and $\chi_{\ell} \geq 0$. It follows that $\operatorname{supp} \nabla \chi_{\ell} \subset \Lambda_{\ell} \backslash \Lambda_{\ell, \delta}$ and $W\left(\chi_{\ell}\right)$ is also localized in this region. The condition we must verify is
$[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right):$
$\exists \gamma_{0}>0$ and $\ell_{0} \gg 1$ such that $\gamma_{0} \ell_{0} \gg 1$ and $\mathbb{P}\left\{\sup _{\varepsilon>0}\left\|W\left(\chi_{\ell_{0}}\right) R_{\Lambda_{\ell_{0}}}(E+i \varepsilon) \chi_{\ell_{0} / 3}\right\|<e^{-\gamma_{0} \ell_{0}} \|\right\} \geq$ $1-\ell_{0}^{-\xi}$, for $E$ near the band edges $\widetilde{B}_{ \pm}$and for some $\xi>2 d$.

We do this in two steps. We first prove that for $\delta>0$ small, dist $\left(\sigma\left(H_{\Lambda, \omega}\right), \widetilde{B}_{ \pm}\right)>\delta$ with good probability. We can then apply the Combes-Thomas result of section 3 to conclude exponential decay at energies $E \in\left(\widetilde{B}_{-}-\delta / 2, \widetilde{B}\right) \cup\left(\widetilde{B}_{+}, \widetilde{B}_{+}+\delta / 2\right)$ with a good probability. We then verify $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ for an appropriate choice of $\gamma_{0}$ and $\ell_{0}$.

We now discuss the location of the spectrum of the finite volume Hamiltonians $H_{\Lambda, \omega}$ in the unperturbed spectral gap. Recall that by (H8) the family $\left\{H_{\omega}\right\}$ has an almost sure spectrum $\Sigma$. The probabitity space is $\Omega=(\operatorname{supp} h)^{\mathbb{Z}^{d}}$.

Lemma 5.1 Suppose $\mu \equiv \mu_{\Lambda, \omega_{0}} \in \sigma_{d}\left(H_{\Lambda, \omega_{0}}\right) \cap\left(B_{-}, B_{+}\right)$for some $\omega_{0} \in \Omega$, then $\mu \in \Sigma$.

Proof: let $\psi_{\omega_{0}}$ be an eigenfunction of $H_{\Lambda, \omega_{0}}$ with eigenvalue $\mu_{\Lambda, \omega_{0}} \equiv \mu: H_{\Lambda, \omega_{0}} \psi_{\omega_{0}}=\mu \psi_{\omega_{0}}$, $\left\|\psi_{\omega_{0}}\right\|=1$. For any $R$ such that $\Lambda \subset \subset \Lambda_{R}$, consider the following events ( for any $\nu>0$ )

$$
I_{R, \nu} \equiv\left\{\omega \in \Omega| | \lambda_{i}\left(\omega_{0}\right)-\lambda_{i}(\omega) \mid \leq \nu\left(6|\Lambda|\|u\|_{\infty}\right)^{-1}, \forall i \in \tilde{\Lambda}\right\}
$$

and

$$
E_{R, \nu} \equiv\left\{\omega \in \Omega| | \lambda_{i}(\omega) \mid<\nu\left(6\left|\tilde{\Lambda}_{R} \backslash \tilde{\Lambda}\right|\|u\|_{\infty}\right)^{-1}, \forall i \in \tilde{\Lambda}_{R} \backslash \tilde{\Lambda}\right\}
$$

Set $B_{R, \nu} \equiv I_{R, \nu} \cap E_{R, \nu}$. Let $\chi \in C^{2}$ be a smoothed characteristic function with supp $\chi \subset \Lambda_{2}$, $\chi \leq 1$, and $\chi \mid \Lambda_{1}=1$. For $R>1$, set $\chi_{R}(x) \equiv \chi\left(R^{-1} x\right)$ so that $\left\|\partial^{\alpha} \chi_{R}\right\|=\mathcal{O}\left(R^{-|\alpha|}\right)$, for $|\alpha|=0,1,2$. Choose $R_{1}$ sufficiently large so $\left\|\chi_{R_{1}} \psi_{\omega_{0}}\right\|>\frac{1}{2}$, and for $R>R_{1}$ define $\psi_{R} \equiv$ $\left\|\chi_{R} \psi_{\omega_{0}}\right\|^{-1} \chi_{R} \psi_{\omega_{0}}$ so $\left\|\psi_{R}\right\|^{=}=1$. Then, by the definition of $\psi_{R}$ and the local Hamiltonians,

$$
\left(H_{\omega}-\mu\right) \psi_{R}=\left(H_{\Lambda, \omega_{0}}-\mu\right) \psi_{R}+\sum_{i \in \tilde{\Lambda}}\left(\lambda_{i}(\omega)-\lambda_{i}\left(\omega_{0}\right)\right) u_{i} \psi_{R}+\sum_{i \in \tilde{\Lambda}_{R} \backslash \Lambda} \lambda_{i}(\omega) u_{i} \psi_{R}
$$

and it follows that for all $\omega \in B_{R, \nu,}$

$$
\begin{equation*}
\left\|\left(H_{\omega}-\mu\right) \psi_{R}\right\| \leq 2\left\|\left[H_{0}, \chi_{R}\right] \psi_{\omega_{0}}\right\|+\frac{1}{3} \nu \tag{5.2}
\end{equation*}
$$

The commutator is estimated as follows: as $H_{0}=(p-A)^{2}+V_{0}$, we have

$$
\begin{equation*}
\left[(p-A)^{2}, \chi_{R}\right] \psi_{\omega_{0}}=-2 i \Delta \chi_{R}(p-A) \psi_{\omega_{0}}-\left(\Delta \chi_{R}\right) \psi_{\omega_{0}} . \tag{5.3}
\end{equation*}
$$

Now $\psi_{\omega_{0}}$ is an eigenfunction of $H_{\Lambda, \omega_{0}}$ and, in particular, $\psi_{\omega_{0}} \in D\left(H_{0}\right)$, so

$$
(p-A)_{j} \psi_{\omega_{0}}=(p-A)_{j}\left(H_{0}-z\right)^{-1}\left(\mu-z-V_{\Lambda, \omega_{0}}\right) \psi_{\omega_{0}}
$$

Setting $z=i \delta, \delta>0$, we obtain

$$
\begin{equation*}
\left\|(p-A)_{j} \psi_{\omega_{0}}\right\| \leq \delta^{-1}\left\|\mu-i \delta-V_{\Lambda, \omega_{0}}\right\|_{\infty} \tag{5.4}
\end{equation*}
$$

which is independent of $R$. Hence, by taking $R$ sufficiently large, it follows from (5.4) that

$$
\left\|\left(H_{\omega}-\mu\right) \psi_{R}\right\| \leq \frac{2}{3} \nu
$$

This shows that for any $\nu>0, \sigma\left(H_{\omega}\right) \cap[\mu-\nu, \mu+\nu] \neq \emptyset$ with probability $\mathbb{P}\left(B_{R, \nu}\right)=$ $\mathbb{P}\left(E_{R, \nu}\right) \mathbb{P}\left(I_{R, \nu}\right)>0$. Since the spectrum of $\left\{H_{\omega}\right\}$ is deterministic, this implies $\mu \in \Sigma$.

Lemma 5.2 Let $\mu_{\Lambda, \omega} \equiv \mu \in \sigma_{d}\left(H_{\Lambda, \omega}\right) \cap\left(B_{-}, B_{+}\right)$, with eigenfunction $\phi_{\omega},\left\|\phi_{\omega}\right\|=1$. Assume that $V_{\Lambda, \omega} \geq 0$. Then we have

$$
\left\langle\phi_{\omega}, V_{\Lambda, \omega} \phi_{\omega}\right\rangle \geq\left[\operatorname{dist}\left(\mu, \sigma\left(H_{0}\right)\right)\right]^{2} M_{\infty}^{-1}
$$

Proof: Since $M_{\infty} V_{\Lambda, \omega} \geq\left(V_{\Lambda, \omega}\right)^{2}$ under the hypothesis that $V_{\Lambda, \omega} \geq 0$, we have

$$
\begin{aligned}
\left\langle\phi_{\omega}, V_{\Lambda, \omega} \phi_{\omega}\right\rangle & =M_{\infty}^{-1}\left\langle\phi_{\omega}, M_{\infty} V_{\Lambda, \omega} \phi_{\omega}\right\rangle \\
& \geq M_{\infty}^{-1}\left\|V_{\Lambda, \omega} \phi_{\omega}\right\|^{2}
\end{aligned}
$$

The eigenvalue equation gives $V_{\Lambda, \omega} \phi_{\omega}=-\left(H_{0}-\mu\right) \phi_{\omega}$, so that

$$
\begin{aligned}
\left\langle\phi_{\omega}, V_{\Lambda, \omega} \phi_{\omega}\right\rangle & \geq M_{\infty}^{-1}\left\|\left(H_{0}-\mu\right) \phi_{\omega}\right\|^{2} \\
& \geq M_{\infty}^{-1}\left[\operatorname{dist}\left(\sigma\left(H_{0}\right), \mu\right)\right]^{2} .
\end{aligned}
$$

## Proposition 5.3

Let $\delta_{ \pm} \equiv \frac{1}{2}\left|\widetilde{B}_{ \pm}-B_{ \pm}\right|$, and for any $0<\delta<\frac{1}{2} M_{\infty}^{-1} \min \left(\delta_{+}, \delta_{-}\right)$, assume that $\lambda_{i}(\omega)<(1-$ $\left.\delta M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2}\right) M, \forall i \in \tilde{\Lambda}$. Then we have

$$
\sup \left\{\sigma\left(H_{\Lambda, \omega}\right) \cap\left(-\infty, \tilde{B}_{-}\right)\right\}<\tilde{B}_{-}-\delta
$$

and

$$
\inf \left\{\sigma\left(H_{\Lambda, \omega}\right) \cap\left(\tilde{B}_{+}, \infty\right)\right\}>\tilde{B}_{+}+\delta
$$

Proof: Without loss of generality, we assume $H_{\Lambda, \omega}$ has an eigenvalue $\mu_{\Lambda, \omega} \equiv \mu \in\left[\tilde{B}_{-}-\delta, \tilde{B}_{\bar{\sim}}\right]$. Furthermore, we can assume that $V_{\Lambda, \omega} \geq 0$, since by Lemma 5.1, we always have $\mu \leq \tilde{B}_{-}$ and the eigenvalues of $H_{\Lambda, \omega}$ are increasing functions of the coupling constants $\left\{\lambda_{i}(\omega) \mid i \in \tilde{\Lambda}\right\}$. This fact follows, for example, from the Feynman-Hellman formula and the positivity of $u$. Indeed, if $\phi_{\omega}$ is an eigenfunction of $H_{\Lambda, \omega}$, so that $H_{\Lambda, \omega} \phi_{\omega}=\mu \phi_{\omega}$, then

$$
\begin{aligned}
\frac{\partial \mu_{\Lambda, \omega}}{\partial \lambda_{i}} & =\left\langle\phi_{\omega}, \frac{\partial H_{\Lambda, \omega}}{\partial \lambda_{i}} \phi_{\omega}\right\rangle \\
& =\left\langle\phi_{\omega}, u_{i} \phi_{\omega}\right\rangle>0 .
\end{aligned}
$$

The family $T(\theta) \equiv H_{0}+\theta V_{\Lambda, \omega}$, for $\theta$ in a small neighborhood of $\theta_{0}=1$, is an analytic type $A$ family which is self-adjoint for $\theta$ real. If $\mu$ has multiplicity $m$, there are at most $m$ functions $\mu^{(k)}(\theta)$, analytic in $\theta$ for $\theta$ near $\theta_{0}=1$, and which satisfy $\lim _{\theta \rightarrow \theta_{0}=1} \mu^{(k)}(\theta)=\mu$. Let $\phi^{(k)}(\theta)$ be an eigenfunction for $\mu^{(k)}(\theta)$, with $\left\|\phi^{(k)}(\theta)\right\|=1$ for $\theta$ real and $|\theta-1|$ small. Applying the Feynman-Hellman formula again, we find

$$
\begin{align*}
\frac{d \mu^{(k)}(\theta)}{d \theta} & =\left\langle\phi(\theta), V_{\Lambda, \omega} \phi(\theta)\right\rangle  \tag{5.5}\\
& =\theta^{-1}\left\langle\phi(\theta),\left(\theta V_{\Lambda, \omega}\right) \phi(\theta)\right\rangle
\end{align*}
$$

We now assume $\lambda_{i}(\omega)<\left(1-\delta M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2}\right) M, \forall i \in \tilde{\Lambda}$, and fix

$$
\begin{aligned}
\theta_{1}=\min _{i \in \widetilde{\Lambda}}\left(\frac{M}{\lambda_{i}(\omega)}\right) & \geq\left(1-\delta M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2}\right)^{-1} \\
& >1
\end{aligned}
$$

Applying Lemma 5.2 to $V_{\Lambda, \omega}$ under these conditions yields

$$
\frac{d \mu^{(k)}(\theta)}{d \theta} \geq \theta^{-1} M_{\infty}^{-1}\left[\operatorname{dist}\left(\mu^{(k)}(\theta), \sigma\left(H_{0}\right)\right)\right]^{2}
$$

Upon integrating over $\left[1, \theta_{1}\right]$, we get, by monotonicity of $\mu^{(k)}(\theta)$ :

$$
\begin{aligned}
\mu^{(k)}\left(\theta_{1}\right) & \geq \mu+\left(\log \theta_{1}\right) M_{\infty}^{-1} \min \left\{\left[\operatorname{dist}\left(\mu^{(k)}\left(\theta_{1}\right), \sigma\left(H_{0}\right)\right)\right]^{2},\left[\operatorname{dist}\left(\mu, \sigma\left(H_{0}\right)\right)\right]^{2}\right\} \\
& \geq \mu+\delta>\tilde{B}_{-}
\end{aligned}
$$

This shows that $\left(H_{0}+\sum_{i \in \tilde{\Lambda}} M u_{i}\right)$ has an eigenvalue outside of $\Sigma$ which contradicts Lemma 5.1.

This proposition is the main technical result. We can now easily compute the probability that $\operatorname{dist}\left(\sigma\left(H_{\Lambda, \omega}\right), \tilde{B}_{ \pm}\right)>\delta$.

Corollary 5.4 For $0<\delta<\frac{1}{2} M_{\infty}^{-1} \min \left(\delta_{+}, \delta_{-}\right)$, we have

$$
\sup \left\{\sigma\left(H_{\Lambda, \omega}\right) \cap\left(-\infty, \tilde{B}_{-}\right)\right\}<\tilde{B}_{-}-\delta
$$

and

$$
\inf \left\{\sigma\left(H_{\Lambda, \omega}\right) \cap\left(\tilde{B}_{+}, \infty\right)\right\}>\tilde{B}_{+}+\delta
$$

with a probability larger than

$$
1-|\Lambda| \max _{X=m, M}\left|\int_{1-\delta M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2} X}^{X} h(s) d s\right|
$$

Proof: The probability that $\lambda_{i}(\omega)<\left(1-\delta M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2}\right) M, \forall i \in \tilde{\Lambda}$, is given by $\left[1-\int_{\left(1-\delta M_{\infty} \Delta^{-2}\right) M}^{M} h(s) d s\right]^{|\Lambda|}$. The corollary now follows by expanding this probability and from Proposition 5.3.

We verify $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ by combining Corollary 5.4 on the location of the spectrum of $H_{\Lambda_{\ell}, \omega}$ and the exponential decay estimate of Theorem 3.3. We note that hypothesis (H6) on the decay of the tail of the density $h$ near the endpoints of its support $m$ and $M$ is essential in order to control the probability in corollary 5.4. We first give the decay estimate for the localized resolvent and then comment on the gradient term.

Proposition 5.5 Let $\chi_{i}, i=1,2$, be two functions with $\left\|\chi_{i}\right\|_{\infty} \leq 1$, supp $\chi_{1} \subset \Lambda_{\ell / 3}$ and supp $\chi_{2}$ localized near $\partial \Lambda_{\ell}$ and $\delta_{ \pm} \equiv \frac{1}{2}\left|\tilde{B}_{+}-\tilde{B}_{-}\right|$. For $\beta>0$ as in (H6), consider any $\nu>0$ such that $0<\nu<4 \beta(2 \beta+3 d)^{-1}$. Then $\exists \ell_{0}^{\star} \equiv \ell_{0}^{\star}\left(M_{\infty}, \delta_{+}, \delta_{-}, M\right)$ such that $\forall \ell_{0}>\ell_{0}^{\star}$ and $\forall E \in\left(\widetilde{B}_{-}-\ell_{0}^{\nu-2}, \tilde{B}_{-}\right] \cup\left[\widetilde{B}_{+}, \widetilde{B}_{+}+\ell_{0}^{\nu-2}\right)$,

$$
\sup _{\varepsilon>0}\left\|\chi_{2} R_{\Lambda_{\ell_{0}}}(E+i \varepsilon) \chi_{1}\right\| \leq e^{-\ell_{0}^{\nu / 3}}
$$

with probability $\geq 1-\ell_{0}^{-\xi}$, for some $\xi>2 d$.

Proof: From Corollary 5.4 and (H6), we compute the probability that $\sigma\left(H_{\Lambda_{\ell_{0}}, \omega}\right)$ is at a distance $\delta=2 \ell_{0}^{\nu-2}$ from $\widetilde{B}_{ \pm}$,

$$
\begin{equation*}
\mathbb{P}\left\{\operatorname{dist}\left(\sigma\left(H_{\Lambda_{\ell_{0}}, \omega}\right), \tilde{B}_{ \pm}\right)>2 \delta\right\} \geq 1-\ell_{0}^{d}\left(2 \ell_{0}^{\nu-2} M_{\infty}\left[\min \left(\delta_{+}, \delta_{-}\right)\right]^{-2} X\right)^{3 d / 2+\beta} \tag{5.6}
\end{equation*}
$$

where $X=m$ for $\tilde{B}_{-}$and $X=M$ for $\tilde{B}_{+}$. A simple computation shows that the right side of (5.6) is bounded below by $1-\ell_{0}^{-\xi}$ for some $\xi>2 d$ provided $\nu$ satisfies $0<\nu<4 \beta(2 \beta+3 d)^{-1}$. We now apply Theorem 3.3 to $H_{\Lambda_{\iota_{0}}, \omega}$. Let $E \in\left[\tilde{B}_{-}-\ell_{0}^{\nu-2}, \tilde{B}_{-}\right)$and, following the notation of Theorem 3.3, let $\Delta_{-} \equiv \operatorname{dist}\left(\tilde{B}_{-}-\delta, E\right)>\delta / 2=\ell_{0}^{\nu-2}$ and $\Delta_{+} \geq\left|\tilde{B}_{+}-\tilde{B}_{-}\right|$. Since $\operatorname{dist}\left(\operatorname{supp} \chi_{2}, \operatorname{supp} \chi_{1}\right) \geq \ell_{0} / 3$ (in dimension $d>9$, this is no longer true; one has to replace $\ell_{0} / 3$ by $\ell_{0} /(3 \sqrt{d})$, for the diameter of the inner cube), we obtain

$$
\begin{aligned}
\left\|\chi_{2} R_{\Lambda_{\ell_{0}}}(E+i \varepsilon) \chi_{1}\right\| & \leq C_{2} \sup \left(\left|\tilde{B}_{+}-\tilde{B}_{-}\right|^{-1}, \ell_{0}^{2-\nu}\right) \\
& \times e^{-\inf \left(\alpha_{0}, C_{1} \ell_{0}^{/ 2-1}\left|\tilde{B}_{+}-\widetilde{B}_{-}\right|^{1 / 2}\right) \ell_{0} / 6}
\end{aligned}
$$

The result follows by taking $\ell_{0}$ large.

Corollary 5.6 $\exists \ell_{0}^{\star}$ such that $\forall \ell_{0}>\ell_{0}^{\star}$, hypothesis $[\mathrm{H} 1]\left(\gamma_{0}, \ell_{0}\right)$ holds $\forall E \in\left(\tilde{B}_{-}-\ell_{0}^{\nu-2}, \tilde{B}_{-}\right] \cup$ $\left[\widetilde{B}_{+}, \widetilde{B}_{+}+\ell_{0}^{\nu-2}\right)$ and any $\nu$ satisfying $0<\nu<4 \beta(2 \beta+3 d)^{-1}, \beta$ as in (H6).

Proof: As in Lemma 5.1, of [6], we write

$$
\begin{align*}
\left\|W\left(\chi_{\ell_{0}, v}\right) R_{\Lambda_{\ell_{0}}} \chi_{\ell_{0} / 3}\right\| \leq & \left\|\left(\Delta \chi_{\ell_{0}, v}\right) R_{\Lambda_{\ell_{0}}} \chi_{\ell_{0} / 3}\right\| \\
& +2 \sum_{j=1}^{d}\left\|\left(\partial_{j} \chi_{\ell_{0}, v}\right)(p-A)_{j} R_{\Lambda_{\ell_{0}}} \chi_{\ell_{0} / 3}\right\| \tag{5.7}
\end{align*}
$$

for a function $\chi_{\ell_{0}, v}$ localized within distance $v$ of $\partial \Lambda_{\ell_{0}}$. Let $\chi_{i}, i=1,2$, be smooth functions such that $\chi_{i} \chi_{\ell_{0}, v}=\chi_{\ell_{0}, v}, \chi_{2} \chi_{1}=\chi_{1}$, and supp $\chi_{i}$ is localized within a distance $2 v$ for $i=1$ and $3 v$ for $i=2$, of $\partial \Lambda_{\ell_{0}}$. Then, we write for each $j$ and any $u \in L^{2}\left(\mathbb{R}^{d}\right)$,

$$
\begin{aligned}
\left\|\left(\partial_{j} \chi_{\ell_{0}, v}\right)(p-A)_{j} R_{\Lambda_{\ell_{0}}} u\right\|^{2} & \leq C_{0}\left\langle(p-A)_{j} R_{\Lambda_{\ell_{0}}} u, \chi_{1}(p-A)_{j} \chi_{2} R_{\Lambda_{\ell_{0}}} u\right\rangle \\
& \leq C_{0}\left\|\chi_{2} R_{\Lambda_{\ell_{0}}} u\right\|\left\|(p-A)_{j} \chi_{1}(p-A)_{j} R_{\Lambda_{\ell_{0}}} u\right\|
\end{aligned}
$$

Taking $u=\chi_{\ell_{0} / 3} f$, we see that (5.7) is bounded above as in Proposition 5.5 (taking $\ell_{0}^{\star}$ larger) provided we have $\left\|(p-A)^{2} R_{\Lambda_{\ell_{0}}} u\right\|$ bounded. This follows with a probability $\geq 1-\ell_{0}^{-\xi}$, since $V_{0}$ is relatively bounded and $V_{\omega}^{\Lambda_{\ell_{0}}}$ is bounded.

## 6 The Case of Unbounded Random Potentials

We indicate here the modifications necessary when $\operatorname{supp} h$ is unbounded and satisfies the second part of (H6). To control the location of $\sigma\left(H_{\Lambda}\right)$ with a good probability, we must work in the weak coupling regime. Consequently, we study the family $H(g)=H_{0}+g V_{\omega}$, for $|g|$ sufficiently small. We assume conditions (H1)-(H8) in this section.

Proposition 6.1 The random family of Schrödinger operators $H_{\omega}(g)=H_{0}+g V_{\omega}$ is essentialy self-adjoint on $C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$ with probability 1.

Proof: We refer to Hinz and Stolz [18] for a discussion of essential self-adjointness. It suffices to prove that $\left|V_{\omega}(x)\right|=\mathcal{O}\left(|x|^{2}\right)$ as $|x| \rightarrow \infty$ with probability one. We define events $A_{k}, k \in \mathbb{Z}^{d}$, by

$$
A_{k} \equiv\left\{\omega| | \lambda_{k}(\omega)\left|\geq 1+|k|^{2}\right\}\right.
$$

From (H6), we have for any bounded set $B \subset \mathbb{R}^{d}$ containing the origin,

$$
\begin{aligned}
\sum_{k \in \mathbb{Z}^{d} \backslash B} \mathbb{P}\left(A_{k}\right) & =\sum_{k \in \mathbb{Z}^{d} \backslash B}\left(\int_{|\lambda|>1+\left|k^{2}\right|} h(\lambda) d \lambda\right) \\
& \leq \frac{C_{h}}{r+1} \sum_{k \in \mathbb{Z}^{d} \backslash B}|k|^{-2(r+1)} \\
& <\infty,
\end{aligned}
$$

since $r>\frac{d}{2}-1$ according to (H6). The Borel-Cantelli lemma then states that $\mathbb{P}\left(\overline{\lim } A_{k}\right)=0$. So $\forall k \in \mathbb{Z}^{d},|k|$ sufficiently large, and for a.e. $\omega \in \Omega, \exists$ finite $C_{\omega}>0$ s.t. $\left|\lambda_{k}(\omega)\right| \leq C_{\omega}\left(1+|k|^{2}\right)$.

We next turn to the Wegner estimate. The only change in Theorem 4.1 is a factor $g^{q}$ on the right side of (4.1). The multiscale analysis of [5] requires a simple modification. For a constant $C_{\ell}$, depending on the length $\ell$, assumption (H6) on the decay of $h(\lambda)$ implies

$$
\begin{equation*}
\mathbb{P}\left\{\left|V_{\Lambda_{\ell}}\right|<C_{\ell}\right\} \geq 1-\frac{2}{r+1}\|u\|_{\infty}^{r} C_{h} \ell^{d} C_{\ell}^{-(r+1)} \tag{6.1}
\end{equation*}
$$

for $C_{h}$ and $r$ as in (H6). It is easy to verify that for $C_{\ell}=\mathcal{O}\left(\ell^{6}\right)$, we have (6.1) bounded below by $1-\ell^{-\xi}$, for some $\xi>2 d$. This can be absorbed into the probability of exponential decay. At each stage of the multiscale analysis the constant is $\mathcal{O}\left(\ell_{n}^{6}\right)$. A careful check of the calculations in the appendix of [5] shows that this changes the decay constant $\gamma$ by a vanishing amount of $\mathcal{O}\left(\left(\log \ell_{n}\right) \ell_{n}^{-1}\right)$ at each step. Hence, the results remain unchanged. Next, we indicate how the small coupling constant $g$ allows us to obtain estimates on $\sigma\left(H_{\Lambda_{\ell}, \omega}(g)\right)$, which replace those of section 5 . In fact, the results are simpler in this case.

Proposition 6.2 Let $E_{m} \equiv\left(\frac{1}{2}\right)\left(B_{+}-B_{-}\right), \Delta \equiv\left(\frac{1}{2}\right)\left|B_{+}-B_{-}\right|$, and fix $K>2$. Then $\exists g_{0}(K)>0$ such that $\forall g<g_{0}(K)$ and for $l_{0}=g^{-6}$,

$$
\mathbb{P}\left\{\operatorname{dist}\left(\sigma\left(H_{\Lambda_{\ell_{0}}, \omega}(g)\right), E_{m}\right)>K^{-1}(K-1) \Delta\right\} \geq 1-l_{0}^{-\xi}
$$

for some $\xi>2 d$.

Proof: It is clear that $\left\|g V_{\Lambda_{\ell}}\right\|_{\infty}<K^{-1} \Delta$, if $\forall i \in \tilde{\Lambda}_{l}$, the coupling constants satisfy

$$
\left|\lambda_{i}(\omega)\right| \leq\left(g K u_{\infty}\right)^{-1} \Delta \equiv \nu(\Delta)
$$

where $u_{\infty} \equiv\left\|\sum_{i \in \mathbb{Z}^{d}} u_{i}\right\|_{\infty}$. If this condition holds, then $\sigma\left(H_{\Lambda_{\ell_{0}}, \omega}\right)$ is a distance $K^{-1}(K-1) \Delta$ from $E_{m}$. The probability of this occurring is

$$
p_{0} \equiv \mathbb{P}\left\{\operatorname{dist}\left(\sigma\left(H_{\Lambda_{\ell_{0}}, \omega}(g)\right), E_{m}\right) \geq K^{-1}(K-1) \Delta\right\} \geq 1-\ell_{0}^{d} \int_{|\lambda|>\nu(\Delta)} h(\lambda) d \lambda .
$$

Using (H6), we obtain the estimate for the probability

$$
p_{0} \geq 1-C_{h} \ell_{0}^{d} g^{q+1}\left(\Delta\left(K u_{\infty}\right)^{-1}\right)^{-(q+1)}
$$

where $q$ and $C_{h}$ are as in (H6). By choosing $l_{0}$ large enough and $g=\mathcal{O}\left(\ell_{0}^{-6}\right)$, we can bound $p_{0}$ from below by $1-\ell_{0}^{-\xi}$, for some $\xi>2 d$.

Finally, we formulate the analog of Proposition 5.5 in this case. We note that Corollary 5.6 is immediate since we know $V_{\Lambda_{\ell_{0}}, \omega}$ can be bounded with a good probability.

Proposition 6.3 Let $\chi_{i}, i=1,2$, be the functions defined in Proposition 5.5 and fix $K>2$ as in Proposition 6.2. There exist finite positive constants $g_{0}(K), \ell_{0}^{*}$ and $C_{3}, C_{4}$ (depending only on $\chi_{i}, K$, and $\left.\Delta\right)$, such that for all $\ell_{0} \gg \ell_{0}^{*}$ and any $E \in\left[B_{-}+2 K^{-1} \Delta, B_{+}-2 K^{-1} \Delta\right]$, we have

$$
\sup _{\varepsilon>0}\left\|\chi_{2} R_{\Lambda_{\ell_{0}}}(E+i \varepsilon) \chi_{1}\right\| \leq C_{3} e^{-C_{4} \ell_{0}}
$$

with probability $\geq 1-l_{0}^{-\xi}$, for some $\xi>2 d$.

Proof: For $E$ as in the proposition, define

$$
\begin{aligned}
& \Delta_{-} \equiv \inf _{B \in\left\{B_{-}, B_{+}\right\}}(\operatorname{dist}(E, B)), \\
& \Delta_{+} \equiv \sup _{B \in\left\{B_{-}, B_{+}\right\}}(\operatorname{dist}(E, B)) .
\end{aligned}
$$

From Proposition 6.2, it follows that for $g<g_{0}(K)$ and $\ell_{0}>g^{-6}$, we have $\Delta_{ \pm} \geq(\Delta / 4)$ with a probability $\geq 1-\ell_{0}^{\xi}$, for some $\xi>2 d$. We can now apply Theorem 3.1 directly. The analog of Corollary 5.6 now follows since we can control $V_{\omega}^{\Lambda_{l}}$ with a good probability ( $\geq 1-\ell^{\xi}$ ), as indicated above.

It remains to provide some examples which show that theorem 2.2 is not empty. We prove that if $\operatorname{supp} h=\mathbb{R}$ and hypotheses (H1)-(H8) are satisfied, then the almost sure spectrum $\Sigma(g)$ fills in the spectral gaps of $H_{0}$; an example of this is the Gaussian distribution. We prove the following.

Proposition 6.4 Let $H_{0}$ satisfy (H1)-(H3) and assume (H5), (H7)-(H8). Let $\Sigma(g)$ be the a.s. spectrum of $H_{\omega}(g)=H_{0}+g V_{\omega}$ and assume supp $h=\mathbb{R}$. Then we have

$$
\mathbb{R} \backslash \sigma\left(H_{0}\right) \subset \Sigma(g), g \neq 0
$$

Proof: We fix $g=1$ without loosing generality and consider $\mu_{0} \in\left(B_{-}, B_{+}\right)$; by Lemma 5.1 one has $\mu_{0} \in \Sigma(g)$ if $\mu_{0} \in \sigma_{d}\left(H_{\Lambda, \omega_{0}}\right)$ for some finite volume hamiltonians $H_{\Lambda, \omega_{0}}$ and some $\omega_{0} \in \Omega$. Given any fixed ball $\Lambda \subset \mathbb{R}^{d}$ there exists by (H5) and (H7) an $\omega_{0} \in \Omega$ such that $V_{\Lambda, \omega_{0}}$ is positive; consider then $H(\lambda) \equiv H_{0}+\lambda V_{\Lambda, \omega_{0}}$, i.e., $H(\lambda)=H_{\Lambda, \lambda \omega_{0}}$; by (H3) and (H7) one has $\sigma_{\text {ess }}(H(\lambda))=\sigma_{\text {ess }}\left(H_{0}\right)$ for all $\lambda$ and the operator $K(\mu)=\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}\left(H_{0}-\mu\right)^{-1}\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}$ is compact for all $\mu \in \rho\left(H_{0}\right)$. It is well known that $\mu_{0} \in \sigma_{d}(H(\lambda))$ iff $-1 / \lambda \in \sigma\left(K\left(\mu_{0}\right)\right)$;
so unless $K\left(\mu_{0}\right)=0$ one has $\mu_{0} \in \overline{U_{\lambda \in \mathbb{R}} \sigma_{d}(H(\lambda))}$. On the other hand, if $K\left(\mu_{0}\right)=0$, then either there exists a sequence $\left(\mu_{n}\right)_{n}$ converging to $\mu_{0}$ such that $K\left(\mu_{n}\right) \neq 0$ in which case $\mu_{0}$ obviously belongs to $\overline{U_{\lambda \in \mathbb{R}} \sigma_{d}(H(\lambda))}$; or $K(\mu)=0$ for all $\mu$ in an open neighbourhood of $\mu_{0}$; but then $\frac{d}{d \mu} K(\mu)_{\mid \mu=\mu_{0}}=\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}\left(H_{0}-\mu_{0}\right)^{-2}\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}$ is zero i.e. $\left(H_{0}-\mu_{0}\right)^{-1}\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}=0$; but $\mu_{0} \in \rho\left(H_{0}\right)$ so this is possible only if $\left|V_{\Lambda, \omega_{0}}\right|^{\frac{1}{2}}=0$. Since Lemma 5.1 implies that $\overline{U_{\lambda \in \mathbb{R}} \sigma_{d}(H(\lambda))} \subseteq \Sigma(g)$, the proof is complete.

We remark that this technique also applies to show (H9) in case supp $h$ is compact but large. Essential in the proof is positivity of $V_{\Lambda, \omega_{0}}$ which follows from positivity of $u$ (assumption (H7)); if there is no magnetic field, $A=0$, we could also use results of Deift and Hempel to get the result without this positivity assumption ([10], [16]).

## 7 Appendix

We prove estimates on the operator $K_{\{i\}}$ defined in (4.10) which are needed in the proof of Theorem 4.1. Let $\tilde{\Lambda} \equiv \Lambda \cap \mathbb{Z}^{d}$ and recall that $\{i\}$ is a $q$-tuple of elements of $\tilde{\Lambda}$. The following lemma is easily proved using Hölder's inequality for trace ideals (see, for example, Theorem 2.8 of [30]).

Lemma 7.1 Assume (H1) - (H3) and (H7). Then $K_{\{i\}}$ is trace class provided $\{i\}$ is a $q$-tuple, with $q$ as in (H3). There exists a finite constant $\widetilde{C}_{E_{0}}>0$, depending only on $\|u\|_{\infty}$, $\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)^{-1}$, and $d \geq 1$, such that $\left\|K_{\{i\}}\right\|_{1} \leq \widetilde{C}_{E_{0}}$.

The main result of this appendix is the following proposition which establishes (4.17).

Proposition 7.2 Under the assumptions of Lemma 7.1, for any $E_{0} \in\left(B_{-}, B_{+}\right), \exists$ finite constant $C_{E_{0}}>0$ such that

$$
\begin{equation*}
\sum_{i_{1}, \ldots, i_{q} \in \tilde{\Lambda}}\left\|K_{\{i\}}\right\|_{1} \leq C_{E_{0}}|\Lambda| \tag{7.1}
\end{equation*}
$$

provided $\{i\}$ is a $q$-tuple, with $q$ as in (H3). The constant $C_{E_{0}}$ depends on the dimension $d \geq 1,\|u\|_{\infty}$, and $\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)^{-1}$.

The work in this appendix concerns only the unperturbed Hamiltonian $H_{0}=(p-A)^{2}+V_{0}$ and $E_{0} \in\left(B_{-}, B_{+}\right) \subset \rho\left(H_{0}\right)$. To simplify the notation, we write $R_{0} \equiv\left(H_{0}-E_{0}\right)^{-1}$.

Lemma 7.3 Assume (H1) - (H3) and (H7). Suppose $\chi_{1}, \chi_{2} \in C^{\infty}\left(\mathbb{R}^{d}\right)$, with supp $\chi_{1}$ compact and that supp $\chi_{2}$ lies in a half-space disjoint from supp $\chi_{1},\left\|\chi_{i}\right\|_{\infty}=1$, dist $\left(\operatorname{supp} \chi_{1}, \operatorname{supp} \chi_{2}\right)$ $\geq a>0$, for some $a>0$.

Then, the operator $\chi_{1} R_{0} \chi_{2} \in \mathcal{J}_{1}$. Furthermore, there exist finite constants $D>0, \alpha>0$ such that

$$
\begin{equation*}
\left\|\chi_{1} R_{0} \chi_{2}\right\|_{1} \leq D e^{-\alpha a} \tag{7.2}
\end{equation*}
$$

where $D$ and $\alpha$ depend only on $\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)^{-1}$.

Proof: Let $H_{1}$ be the half-space containing $\operatorname{supp} \chi_{1}$ and such that

$$
H_{1}\left\{x \mid \operatorname{dist}\left(x, \operatorname{supp} \chi_{1}\right)<\operatorname{dist}\left(x, \operatorname{supp} \chi_{2}\right)\right\}
$$

Let $L$ be the straight line minimizing dist $\left(\operatorname{supp} \chi_{1}, \operatorname{supp} \chi_{2}\right)$ so $|L|=a$ and $\partial H_{1} \perp L$. Let $T_{\lambda}$, $\lambda>0$, denote the parallel translate of $H_{1}$ along $L$, that is, $T_{\lambda} H_{1}=\left\{x \mid \lambda^{-1} \operatorname{dist}\left(\operatorname{supp} \chi_{1}, x\right)<\right.$ $\left.\operatorname{dist}\left(\operatorname{supp} \chi_{2}, x\right)\right\} \equiv H_{\lambda}$. For any $\lambda>1$, we can choose $\chi_{\lambda} \in C_{0}^{\infty}$ such that $\chi_{1} \chi_{\lambda}=\chi_{1}$ and $\operatorname{dist}\left(\operatorname{supp} \chi_{\lambda}, \operatorname{supp} \chi_{2}\right)=a\left(1-\frac{1}{\lambda}\right)$. Note that $\chi_{\lambda} \chi_{2}=0$ if $\lambda>1$. Iterating the geometric resolvent equation $2 q$-times, we find

$$
\begin{equation*}
\chi_{1} R_{0} \chi_{2}=\chi_{1} R_{0} W\left(\chi_{\lambda_{1}}\right) R_{0} W\left(\chi_{\lambda_{2}}\right) \ldots W\left(\chi_{\lambda_{2 q}}\right) R_{0} \chi_{2} \tag{7.3}
\end{equation*}
$$

for any sequence $\lambda_{1}>\lambda_{2}>\cdots \lambda_{2 q}>1$, where

$$
\begin{equation*}
W\left(\chi_{\lambda}\right)=\left[H_{0}, \chi_{\lambda}\right]=\left[(p-A)^{2}, \chi_{\lambda}\right] . \tag{7.4}
\end{equation*}
$$

For each $\lambda_{i}$, we can find $\tilde{\chi}_{\lambda_{i}} \in C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$ such that $W\left(\chi_{\lambda_{i}}\right) \tilde{\chi}_{\lambda_{i}}=W\left(\chi_{\lambda_{i}}\right)$. It then follows for $q$ as in (H3) and the boundedness of $W\left(\chi_{\lambda}\right) R_{0} W\left(\chi_{\lambda^{\prime}}\right)$ that

$$
\begin{equation*}
\tilde{\chi}_{\lambda_{i}} R_{0} W\left(\chi_{\lambda_{i+1}}\right) R_{0} W\left(\chi_{\lambda_{i+2}}\right) \in \mathcal{J}_{q} \tag{7.5}
\end{equation*}
$$

In exactly the same way as in the proof of Lemma 7.1, we use the Hölder inequality to conclude that $\chi_{1} R_{0} \chi_{2} \in \mathcal{J}_{1}$. To prove the exponential decay estimate (7.2), we use the Combes-Thomas estimate.

If $\delta\left(E_{0}\right) \equiv \operatorname{dist}\left(E_{0}, \sigma\left(H_{0}\right)\right)^{-1}$, then there exist finite constants $C>0, \tilde{c}>0$ depending on $\delta$, s.t.

$$
\begin{equation*}
\left\|\chi_{1} R_{0} \chi_{2}\right\| \leq C e^{-\tilde{\alpha} a} \tag{7.6}
\end{equation*}
$$

By the same argument as above, we can choose $\tilde{\chi}_{1} \in C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$ such that $\tilde{\chi}_{1} \chi_{1}=\chi_{1}, \tilde{\chi}_{1} \chi_{2}=0$ and

$$
\begin{aligned}
& \operatorname{dist}\left(\operatorname{supp} \chi_{1}, \operatorname{supp} \nabla \tilde{\chi}_{1}\right)>a / 3 \\
& \operatorname{dist}\left(\operatorname{supp} \tilde{\chi}_{1}, \operatorname{supp} \chi_{2}\right)>a / 3
\end{aligned}
$$

Again, by the support properties,

$$
\chi_{1} R_{0} \chi_{2}=\chi_{1} R_{0} W\left(\tilde{\chi}_{1}\right) R_{0} \chi_{2}
$$

and we estimate the trace norm by

$$
\begin{equation*}
\left\|\chi_{1} R_{0} \chi_{2}\right\|_{1} \leq\left\|\chi_{1} R_{0} \tilde{\chi}_{1}\right\|\left\|W\left(\tilde{\chi}_{1}\right) R_{0} \chi_{2}\right\|_{1} \tag{7.7}
\end{equation*}
$$

where $\tilde{\chi}_{1}$ is the characteristic function for $\operatorname{supp}\left(\nabla \tilde{\chi}_{1}\right)$.
To prove the finiteness of the second factor, we note

$$
\begin{equation*}
W\left(\tilde{\chi}_{1}\right) R_{0} \chi_{2}=i \nabla \tilde{\chi}_{1} \cdot(p-A) R_{0} \chi_{2}+\Delta \tilde{\chi}_{1} R_{0} \chi_{2} \tag{7.8}
\end{equation*}
$$

The second term on the right in (7.8) is trace class by the first part of the theorem. The first term is trace class by the argument of (7.3) - (7.5). Applying the estimate (7.6) to the first factor in (7.7) gives the result (7.2). Note that $C$ depends on $\left\|W\left(\chi_{\lambda_{1}}\right) R_{0} W\left(\chi_{\lambda_{2}}\right)\right\|$, which is proportional to $\operatorname{dist}\left(E_{0}, \sigma\left(H_{0}\right)\right)^{-1}$.

Remark : We will only use this lemma for $\chi_{1}, \chi_{2} \in C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$. In the proof of Proposition 7.2 below, we simplify notation and write

$$
K_{\{i\}}=u_{i_{1}} R_{0} u_{i_{2}} R_{0} u_{i_{3}} \ldots u_{i_{l-1}} R_{0}^{2} u_{i_{q}}
$$

and assume $u_{i_{k}}^{2}=u_{i_{k}}$, when convenient.
Proof of Proposition 7.2: Fix $q$ so that $K_{i_{1} \ldots i_{q}} \in \mathcal{J}_{1}$ according to Lemma 7.1. We separate the multiple sum over $\tilde{\Lambda}^{q}=\left\{\left(i_{1}, \ldots, i_{q}\right) \mid i_{k} \in \tilde{\Lambda}\right\}$ into two parts. By (H5), we can choose a finite $a>0$ so that if $\eta \equiv 2 \operatorname{diam}(\operatorname{supp} u)$, we have $\eta<a<2 \eta$ and $\left\|i_{n}-i_{m}\right\|>a$ implies $\operatorname{dist}\left(\operatorname{supp} u_{i_{n}}, \operatorname{supp} u_{i_{m}}\right)>a / 2>0$. We define a subset $I_{\tilde{\Lambda}}$ of $\tilde{\Lambda}^{q}$ as follows. An $q$-tuple $\{i\} \in \widetilde{\Lambda}^{q}$ is in $I_{1}$ if $\left\|i_{k-1}-i_{k}\right\|<a \forall k=2, \ldots, q$. Let $I_{2} \equiv \tilde{\Lambda}^{q} \backslash I_{1}$ be the complementary set of indices. If $\{i\} \in I_{2}$, then there exist at least one pair of consecutive indices ( $i_{k-1}, i_{k}$ ) s.t. $\left\|i_{k}-i_{k-1}\right\|>a$. We use this pair of indices for the exponential decay. From Lemma 7.1, we have an estimate for the sum over $I_{1}$,

$$
\begin{equation*}
\sum_{\{i\} \in I_{1}}\left\|K_{\{i\}}\right\|_{1} \leq \tilde{C}_{E_{0}}\left|I_{1}\right| \tag{7.9}
\end{equation*}
$$

where $\widetilde{C}_{E_{0}}$ is the constant appearing in Lemma 7.1. To estimate $\left|I_{1}\right|$, if we fix $i_{1}$, there are a finite number $C(a, d)$ of possible $i_{2}$ terms so that $\left\|i_{1}-i_{2}\right\|<a$. This number depends only on the constant $a$ and $d$, for all large $\Lambda$. Hence, for fixed $i_{1}$, there are $C(a, d)^{q-1}$ terms satisfying the closeness condition since there are $|\tilde{\Lambda}|$ choices for $i_{1}$, we obtain the bound

$$
\begin{equation*}
\left|I_{1}\right| \leq \tilde{C}(a, d)|\Lambda| \tag{7.10}
\end{equation*}
$$

We now turn to the sum over $I_{2}$. We write $i_{j} \cap i_{k}$ if $\left\|i_{j}-i_{k}\right\|<a$ and $i_{j} \cap i_{k}$ if $\left\|i_{j}-i_{k}\right\|>$ a. We sum successively from $i_{1}$ to $i_{q}$, for $\{i\} \in I_{2}$. We sum first over all $i_{1}$ such that $\exists\left(i_{2}, i_{3}, \ldots, i_{q}\right) \in \tilde{\Lambda}^{q-1}$ s.t. $\left(i_{1}, i_{2}, \ldots, i_{q}\right) \in I_{2}$. We separate the $i_{1}$ sum into two parts :

$$
\begin{equation*}
\sum_{i_{1}}\left\|K_{\{i\}}\right\|_{1}=\left(\sum_{i_{1} \cap i_{2}}+\sum_{i_{1} \not x_{i_{2}}}\right)\left\|K_{\{i\}}\right\|_{1} \tag{7.11}
\end{equation*}
$$

The sum over $i_{1}$ s.t. $i_{1} \cap i_{2}$ is bounded above by

$$
\begin{equation*}
\sum_{i_{1} \cap i_{2}}\left\|u_{i_{1}} R_{0} u_{i_{2}}\right\|\left\|u_{i_{2}} R_{0} \cdots R_{0}{ }^{2} u_{i_{q}}\right\|_{1} \leq C(a, d) \delta\left(E_{0}\right)\left\|u_{i_{2}} R_{0} \cdots R_{0}^{2} u_{i_{q}}\right\|_{1} \tag{7.12}
\end{equation*}
$$

where $\delta\left(E_{0}\right) \equiv\left(\operatorname{dist}\left(\sigma\left(H_{0}\right), E_{0}\right)\right)^{-1}$ and $C(a, d)$ are the numbers introduced above. To evaluate the sum for which $i_{1} \wedge i_{2}$, we use (7.2) of lemma 7.3, and obtain an upper bound,

$$
\begin{equation*}
\sum_{i_{1} \not \supset i_{2}}\left\|u_{i_{1}} R_{0} u_{i_{2}}\right\|\left\|_{1}\right\| u_{i_{2}} R_{0} \ldots . R_{0}{ }^{2} u_{i_{q}}\left\|\leq\left(\sum_{i_{1} \nsubseteq i_{2}} D e^{-\alpha\left\|i_{1}-i_{2}\right\|}\right)\right\| u_{i_{2}} R_{0} \ldots . R_{0}^{2} u_{i_{q}}\| \| u \|_{\infty}^{2} . \tag{7.13}
\end{equation*}
$$

The sum in (7.13) is finite and independent of $|\Lambda|$. Note that in (7.13), we only need to continue the estimate in the operator norm. We now pass to the sum over $i_{2}$. There are two terms, one coming from (7.12) and one from (7.13). From (7.12), we sum over all $i_{2}$ such that $\left(i_{2}, i_{3}, \ldots . i_{q}\right) \in \tilde{\Lambda}^{q-1} \cap I_{2}$. Separating the sum into 2 terms as in (7.11), we obtain,

$$
\begin{align*}
\sum_{i_{2}}\left\|u_{i_{2}} R_{0} \ldots R_{0}^{2} u_{i_{q}}\right\|_{1} \leq & \sum_{i_{2} \cap i_{3}}\left\|u_{i_{2}} R_{0} u_{i_{3}}\right\|\left\|u_{i_{3}} R_{0} \ldots . R_{0}^{2} u_{i_{q}}\right\|_{1} \\
& +\sum_{i_{2} \not i_{3}}\left\|u_{i_{2}} R_{0} u_{i_{3}}\right\|\left\|_{1}\right\| u_{i_{3}} R_{0} \ldots R_{0}^{2} u_{i_{q}} \| . \tag{7.14}
\end{align*}
$$

Each term is estimated as in (7.12)-(7.13). As for the $i_{2}$-sum in (7.13), we have

$$
\begin{align*}
\sum_{i_{2}}\left\|u_{i_{2}} R_{0} u_{i_{3}} \cdots R_{0}{ }^{2} u_{i_{q}}\right\| & \\
& \leq \sum_{i_{2} \cap i_{3}}\left\|u_{i_{2}} R_{0} u_{i_{3}}\right\|\left\|u_{i_{3}} R_{0} \cdots R_{0}{ }^{2} u_{i_{q}}\right\| \\
& +\sum_{i_{2} \not \prod_{i_{3}}}\left\|u_{i_{2}} R_{0} u_{i_{3}}\right\|\left\|u_{i_{3}} R_{0} \cdots R_{0}{ }^{2} u_{i_{q}}\right\| \tag{7.15}
\end{align*}
$$

Since the trace norm has been evaluated in (7.13); the usual Combes-Thomas result (7.6) (see section 3) can be used for the second term of (7.15). As above, the bound on both terms is $|\Lambda|$-independent. We continue to sum over $i_{3}, \cdots i_{q-2}$. In (7.14) the trace norm is pushed through each pair when $\left(i_{j-1}, i_{j}\right)$ satisfy $\left\|i_{j-1}-i_{j}\right\|<a$, and it is evaluated using lemma 7.3 otherwise. Similarly, in (7.15), we use the Combes-Thomas result (7.6) of section 3 to control the operator norm of pairs $\left(i_{j-1}, i_{j}\right)$ s.t. $\left\|i_{j-1}-i_{j}\right\|>a$. We obtain in this way $2^{q-2}$ terms and a coefficient depending only on $d,\|u\|_{\infty}, C(a, d)$, and $\delta\left(E_{0}\right)$ Finally, there are 2 remaining terms to evaluate : one from (7.14),

$$
\begin{equation*}
\sum_{i_{q-1}, i_{q}}\left\|u_{i_{q-1}} R_{0}{ }^{2} u_{i_{q}}\right\|_{1} \tag{7.16}
\end{equation*}
$$

and the other from (7.15),

$$
\begin{equation*}
\sum_{i_{q-1}, i_{q}}\left\|u_{i_{q-1}} R_{0}{ }^{2} u_{i_{q}}\right\| \tag{7.17}
\end{equation*}
$$

for the trace norm in (7.16), we recall that the remaining indices, coming from $I_{2}$, satisfy $i_{q-1} \cap i_{q}$ (that is, the only remaining trace norm is from those $q$-tuples $\{i\}$ for which only the pair $\left(i_{q-1}, i_{q}\right)$ satisfy $\left.\left\|i_{q-1}-i_{q}\right\|>a\right)$. Because $\operatorname{dist}\left(\operatorname{supp} u_{i_{q-1}}, \operatorname{supp} u_{i_{q}}\right) \geq \frac{a}{2}$, we can find $\chi \in C_{0}^{\infty}\left(\mathbb{R}^{d}\right)$ s.t. $\chi u_{i_{q-1}}=u_{i_{q-1}}, \operatorname{dist}\left(\operatorname{supp} \chi, \operatorname{supp} u_{i_{q}}\right) \geq \frac{a}{4}$, and $\operatorname{dist}\left(\operatorname{supp} \nabla \chi, \operatorname{supp} u_{i_{q-1}}\right) \geq \frac{a}{4}$. We then have:

$$
\begin{align*}
& \sum_{i_{q-1} \not x_{i_{q}}}\left\|u_{i_{q-1}} R_{0}{ }^{2} u_{i_{q}}\right\|_{1} \leq \sum_{i_{q-1} \not x_{i_{q}}}\left\|u_{i_{q-1}} R_{0}\right\|\left\|\chi R_{0} u_{i_{q}}\right\|_{1} . \\
&+\sum_{i_{q-1} \not x_{i_{q}}}\left\|u_{i_{q-1}} R_{0} W(\chi)\right\|_{1}\left\|R_{0}{ }^{2} u_{i_{q}}\right\| \tag{7.18}
\end{align*}
$$

The trace norms in both terms on the right in (7.18) are exponentially bounded by Lemma 7.3 and the operator norms are bounded by a power of $\delta\left(E_{0}\right)$. Consequently, the $i_{q-1^{-}}$ sum is controlled and the $i_{q}$-sum results in a factor of $|\Lambda|$. Finally, we estimate (7.17). We separate the sum into $i_{q-1} \cap i_{q}$ and $i_{q-1} \cap i_{q}$. The nearest neighbour sum is bounded by $C(a, d) \delta\left(E_{0}\right)^{2}|\Lambda|$. The sum over disjoint pairs is estimated as in (7.18) using the usual Combes-Thomas estimate (7.6) for the operator norm. This completes the proof.

Proposition 7.4 Let $K_{0} \equiv R_{0} V_{\Lambda}$, then there exists a finite constant $C>0$, as in Proposition 7.2, such that

$$
\begin{equation*}
\mathbb{E}\left(\left\|K_{0}\right\|_{q}^{q}\right) \leq C|\Lambda| . \tag{7.19}
\end{equation*}
$$

Proof: The proof uses almost exactly the same arguments as in Proposition 7.2 and we will indicate how to reduce the expression to those calculations. By hypothesis (H3), we write $q=2 p$, for some integer $p$. From the definition of the norms, we have

$$
\begin{equation*}
\left\|K_{0}\right\|_{q}^{q}=\left\|\left|K_{0}\right|^{q / 2}\right\|_{1}=\left\|\left(K_{0}^{*} K_{0}\right)^{p}\right\|_{1} . \tag{7.20}
\end{equation*}
$$

Since $K_{0}^{*} K_{0}=R_{0} V_{\Lambda}^{2} R_{0}$, we must estimate

$$
\begin{equation*}
\mathbb{E}_{\Lambda}\left\{\operatorname{Tr}\left(V_{\Lambda}^{2} R_{0}^{2} \cdots V_{\Lambda}^{2} R_{0}^{2}\right)\right\} \tag{7.21}
\end{equation*}
$$

Expanding the potential as before (4.9), we obtain the analog of (4.10),

$$
\begin{equation*}
K_{\{i\}}=u_{i_{1}} R_{0}^{2} u_{i_{2}} u_{i_{3}} R_{0}^{2} u_{i_{4}} u_{i_{5}} \ldots u_{i_{q-1}} R_{0}^{2} u_{i_{q}} . \tag{7.22}
\end{equation*}
$$

The trace norm of this operator is estimated as in the proof of Proposition 7.2. We carry out the summation over the indices in the same manner using Lemma 7.3 to control $\left\|u_{i} R_{0}^{2} u_{j}\right\|_{1}$ when $u_{i} u_{j}=0$. Note that the intermediate terms like $u_{i_{4}} u_{i_{5}}$ actually vanish when the supports are disjoint. The proof then proceeds as in the proof of Proposition 7.2.
