PRAXIS

Gender ratio of offspring and exposure to shortwave radiation among female physiotherapists

First published in: *Scandinavian Journal of Work, Environment & Health* 1994, vol. 20, pp. 345–348. Reproduced with permission.

• **Objectives:** The goal of this study was to investigate whether the deficit of male births found among the offspring of Danish physiotherapists exposed to shortwave radiation during the first month of their pregnancy could be confirmed among the offspring of physiotherapists from Switzerland.

• **Methods:** A self-administrated questionnaire was mailed (two mailings) to all of the 2846 female members of the Swiss Federation of Physiotherapists. It included questions on the gender and birthweight of all children of the physiotherapists, as well as on the use of shortwave or microwave equipment during the first month of each pregnancy. The response rate was 79.5 %, and the analysis was based on 1781 pregnancies.

• **Results:** The gender ratio (the number of males per number of females x 100) was 107 with a 95 % confidence interval (95 % CI) of 89–127 for the 508 pregnancies exposed to shortwave radiation and 101 (95 % CI 90–113) for the 1273 unexposed pregnancies. There was no trend in the gender ratio with increasing intensity or duration of exposure. The prevalence of low birthweight (≤ 2500 g) was not related to exposure to shortwave radiation for either the boys or the girls.

• **Conclusions:** No atypical gender ratio was found for the children of female physiotherapists from Switzerland who had been exposed to shortwave radiation at the beginning of pregnancy. The findings of the Danish study could not be confirmed.

• **Key terms:** birthweight, electromagnetic radiation, epidemiology, male embryo, microwave diathermy, pregnancy outcome, reproductive hazard.

In a case-referent study among the female members of the Union of Danish Physiotherapists, Larsen et al. (1,2) investigated the

reproductive hazards of exposure to high-frequency electromagnetic radiation from shortwave diathermy. No significant association was found between various indices of exposure and congenital malformations, spontaneous abortion or stillbirth and death within one year. However, an association was found between exposure during the first month of pregnancy and a deficit of male births. The gender ratio (number of males per number of females x 100) of offspring was 151 for the physiotherapists with no exposure, 48 for those with low exposure, and 31 for those with high exposure. The trend was significant at the 0.1 % level. In addition there was

an association, although not significant, between exposure and low birthweight among the boys, while there was no such association among the girls. To explain the deficit of male births among the offspring of exposed physiotherapists, it was suggested that this type of electromagnetic radiation could induce very early abortion at a preclinical stage. This occurrence would mainly involve male embryos, which are considered to be more fragile than female ones.

The aim of the present study was to investigate whether the findings by Larsen et al. could be confirmed among physiotherapists from Switzerland.

Subjects and methods

In Switzerland, about 95 % of self-employed physiotherapists and about 60 % of salaried physiotherapists are members of the Swiss Federation of Physiotherapists. A

	30 cm ^a	100 cm ^a
Plate electrodes (Schliephake)	200.0	2.0
Diplode	20.0	1.5
Circuplode	1.0	< 0.1

^a Distance from the electrode

questionnaire was sent to all of the 2846 female members of that federation in November 1992 and a second time in the spring of 1993 to those who did not answer the first request. The physiotherapist was questioned on the gender and the birthweight of all her children, whether born alive or dead. Abortions were excluded because the gender of the fetus was unknown. The physiotherapist was also asked to report for each pregnancy whether she had been exposed to shortwaves during the first month and whether the equipment had been used by her or any colleague. Further questions asked for estimates of the duration of exposure per week at distances from the equipment of 1 m or less and of more than 1 m. The different types of electrodes, as well as the relative percentages of them was also requested. The limit of 1 m was chosen because the electric field strength was shown to fall to 10% at 1.0 m and to 2% at 2.0 m (3). An additional question concerned exposure to microwave radiation.

The questionnaire was returned by 2263 physiotherapists (79.5%), of which 1187 responded by indicating that they had no children, 1030 had one child or more, and 46 either indicated unwillingness to participate or gave uninterpretable answers. The analysis was based on 1781 pregnancies, of which 54% had occurred during the last decade (1983–1992), 31% during the preceding decade (1973–1982), and 15% before 1973.

Measurements in Denmark (3, 4) and Geneva (table 1) indicated that exposure to electromagnetic radiation is very low for the circuplode electrode. This is also the case for the other types of electrode at a distance of 1 m or more. The results were thus analyzed separately for the relatively highly exposed subgroup (i.e. those exposed to monode, diplode or plate electrodes at a distance of 1 m or less).

Table 2: Gender ratio^a of the offspring of physiotherapists by occupational exposure to shortwaves during the first month of pregnancy (95 % CI = 95 % confidence interval)

Group	Number of births		Gender ratio	95 % CI
	Males	Females		
Unexposed	641	632	101	90–113
Exposed	262	246	107	89–127
Total	903	878	103	94–113

^a The number of males per the number of females x 100

For more than one century, the gender ratio of live births in Switzerland has been remarkably stable at around 105. We have assumed that this figure is the «true» gender ratio of the offspring of unexposed physiotherapists. The 95 % confidence interval (95 % CI) for the gender ratio among various subgroups of physiotherapists has been calculated with the use of the exact binomial confidence limits from Geigy Scientific Tables (5).

From our knowledge, the type of equipment used for shortwave diathermy in Switzerland is similar to that used in Denmark. Larsen and Skotte extensively studied the exposure of Danish physiotherapists giving diathermy (3, 4). By a limited series of measurements in Geneva, we were able to verify that the exposure of physiotherapists from Switzerland was likely to be of the same order of magnitude as that of their colleagues in Denmark.

Measurements were carried out in the vicinity of one of the diathermy installations of the School of Physiotherapy, Geneva, being of the type Curaplus 419 operating at 600 W peak power (260 Weff) and a frequency of 27/12 MHz, to determine the potential radiofrequency exposure of therapists during treatment. These measurements were carried out with a Narda model 8608 broadband isotropic radiation monitoring system using a model 8662 B probe which measures the E field.

The measurements were made under normal operating conditions with the electrodes placed on the legs of a patient. Exposure was determined at distances of 30 and 100 cm from the electrode next to the patient. The results are given in table 1. These values should be considered as upper limits of exposure since measurements of the H field showed considerably lower values at the same distances. It can be seen that exposure is a strong function of the type of electrode used, particularly at the shorter distance.

Moreover, it can be postulated that, due to the introduction of the circuplode electrode in the early 1970s, exposure of physiotherapists has been lower during the last two decades than beforehand.

PRAXIS

Results

As shown in table 2, the gender ratio of offspring was 107 (95 % CI 89–127) for physiotherapists exposed to shortwaves at the beginning of pregnancy, whereas it was 101 (95 % CI 90–113) for unexposed physiotherapists. The gender ratio was neither related to the type of electrode (on which the intensity of the electromagnetic field mainly depends) (table 3) nor to the duration of exposure (table 4). The prevalence of low birthweight (≤ 2500 g) was not related to exposure among either the boys or the girls (table 5). Among all of the subgroups exposed to shortwaves, and among the physiotherapists exposed to microwaves (table 6), the 95 % confidence interval of the gender ratio included the expected population value of 105.

There was no significant difference between the exposed

and unexposed physiotherapists (chi-square test) in the gender ratio of offspring (tables 2 and 6) or in the prevalence of low birthweights of offspring (table 5). Moreover the analysis by three periods of birth (1983–1992, 1973–1982 and before 1973) did not show a trend in the gender ratio of offspring among all of the physiotherapists and among the exposed or the unexposed groups.

Discussion

In the present study, there was no suggestion of a deficit of male births or of an increased prevalence of low birthweight of boys among the offspring of physiotherapists exposed to shortwave radiation in Switzerland at the beginning of pregnancy. This result is contrary to the finding of Larsen et al. in Denmark. Among Danish physiotherapists the find-

ing of a significant trend in the gender distribution of the offspring with increasing exposure to electromagnetic radiation was strongly influenced by the extraordinary gender ratio of 151 in the unexposed group (time-weighted exposure index = 0). The 95 % confidence interval for that ratio is 112 to 206, whereas the gender ratio for all births in Denmark is 105.8 (1). Nevertheless, Larsen et al. also found a large deficit of male births in their exposed group (time-weighted exposure index = 1 and 2), for whom the gender ratio was only 42. The current study was large enough to have a power in excess of 99 % to detect, as significant at the 1 % level, a decrease in the gender ratio to Larsen's value of 42. However, we found no suggestion of any deficit in male births.

Animal experiments with pregnant rats or mice exposed to shortwave or microwave radiation have shown increases in malformations and in embryo lethality, as well as reduction in fertility (1). It remains unclear, however, whether these adverse outcomes were only due to the well-known harmful effects of hyperthermia or whether they could be attri-

Table 5: Prevalence of low birthweight of ≤ 2500 g of the offspring^a of physiotherapists by exposure to shortwaves

Group	Low birthweight			
	Males		Females	
	N	%	N	%

butable to a possible nonthermal effect of electromagnetic radiation (1). The gender ratio of the offspring was not reported in these studies.

Two previous studies (6, 7) have addressed the possible reproductive hazard of various types of equipment used by female physiotherapists, but none has included an analysis of the gender ratio. In the first study, the frequency of use of shortwave equipment was significantly associated with congenital malformations in Finland, but only in the lower exposure group (6). In the second study, there was an association of borderline significance between frequent exposure to shortwaves and dead or malformed infants in Sweden, but there was little evidence that this association was causal (7). In neither of the studies, however, was the type of electrode taken into account to classify the exposure of physiotherapists, even though this is an extremely important variable.

In conclusion, the evidence from the available studies that occupational exposure of female physiotherapists to shortwave radiation may be harmful to their offspring is not conclusive.
